## **BACKGROUND OF THE INVENTION**

The present application claims the benefit of U.S. Provisional Application Serial Number 60/137,665 filed on June 4, 1999. The entire text of the above-referenced disclosure is herein incorporated by reference.

### **A. Field of the Invention**

The present invention relates generally to the fields of biochemistry, molecular biology, and virology. More particularly, it relates to the identification of 259 nucleotides of previously unrecognized sequence located at the 3' end of the GB virus B (GBV-B) genome.

### **B. Description of Related Art**

Chronic hepatitis C is a major threat to the public health. Serologic surveys suggest that as many as 3.9 million Americans are chronically infected with the responsible virus, hepatitis C virus (HCV) (Alter, 1997). These individuals are at increased risk of developing progressive hepatic fibrosis leading to cirrhosis and loss of hepatocellular function, as well as hepatocellular carcinoma. The course of chronic hepatitis C is typically lengthy, often extending over decades, with insidious clinical progression usually occurring in the absence of symptoms. Nonetheless, liver disease due to HCV results in the death of 8,000-10,000 Americans annually, and chronic hepatitis C is the most common cause of liver transplantation within the U.S.

Therefore, HCV is a major public health problem. However, therapy for chronic hepatitis C is problematic. Recombinant interferon- $\alpha$  is approved for treatment of chronic hepatitis C (Consensus Development Panel, 1997). The benefit of interferon- $\alpha$  results primarily from its antiviral properties and its ability to inhibit production of virus by infected hepatocytes (Neumann *et al.*, 1998). Nonetheless, even under optimal therapeutic regimens, the majority of patients with chronic hepatitis C fail to eliminate the virus or resolve their liver disease. Treatment failures are especially common in

persons infected with genotype 1 HCV, unfortunately the most prevalent genotype in the U.S. Thus, there is an urgent need to better understand the virus and develop better treatment. Unfortunately, technical difficulties in working with HCV have made it necessary to use infectious surrogate viruses in efforts to develop treatments and vaccines for HCV.

Scientists' efforts to better understand HCV and to develop new drugs for treatment of hepatitis C have been stymied by two overwhelming technical deficiencies: first, the nonexistence of a high permissive cell line that supports replication of the virus and second, the absence of a permissive animal species other than chimpanzees, which are endangered and therefore available on a limited basis.

Presently, those who are working on HCV treatment and prevention are employing an infectious chimeric virus of sindbis and HCV and/or an infectious clone of pestiviruses as surrogate virus models in HCV drug discovery efforts, due to the above technical difficulties of working with HCV. Alternatively, they are using isolated proteins or RNA segments of HCV for biochemical and structural studies. This approach precludes functional studies of virus replication and its inhibition.

GBV-B is a hepatotropic flavivirus that has a unique phylogenetic relationship to human HCV and strong potential to serve as a surrogate virus in drug discovery efforts related to hepatitis C antiviral drug development. GBV-B causes acute hepatitis in experimentally infected tamarins (Simons *et al.*, 1995; Schlauder *et al.*, 1995; Karayiannis *et al.*, 1989) and can serve as a surrogate virus for HCV in drug discovery efforts (due to technical difficulties in working with HCV). GBV-B virus is much closer in sequence and biological properties than the above-described models. It will be easier to make biologically relevant chimeras between HCV and GBV-B than by using more distantly related viruses. GBV-B is hepatotropic (as is HCV), whereas the viruses used in these competing technologies are not. In view of the above, an infectious clone of GBV-B would be useful to those working on HCV treatment and prevention.

Unfortunately, the use of GBV-B as a surrogate or model for HCV has not been possible in the past, because no infectious molecular clone of GBV-B virus genome could be prepared. It is now known that this obstacle was encountered because the GBV-B genome was believed to be 259 nucleotides shorter than its actual length (Muerhoff *et al.*, 1995; Simons *et al.*, 1995). Others, previous to the inventors, had failed to realize that the 3' sequence of GBV-B was missing from the prior sequences. Without this 3' sequence, it is not possible to prepare an infectious GBV-B molecular clone.

## SUMMARY OF THE INVENTION

As discussed above, an infectious molecular clone of GBV-B would be very useful for the development of HCV preventative and therapeutic treatments. The construction of an infectious molecular clone of this virus will require the newly determined 3' sequence to be included in order for the clone to be viable. The inventors have elucidated the previously unrecognized 3' terminal sequence of GBV-B (SEQ ID NO:1). This sequence has been reproducibly recovered from tamarin serum containing GBV-B RNA, in RT-PCR protocols using several different primer sets, and as a fusion with previously reported 5' GBV-B sequences.

The newly identified 3' sequence is not included in published reports of the GBV-B sequence, nor described in patents relating to the original identification of the viral sequence (see U.S. Patent No. 5,807,670 and references therein).

The invention has utility in that the inclusion of the sequence will be necessary for construction of an infectious molecular GBV-B clone. Such clones clearly have the potential to be constructed as chimeras including relevant hepatitis C virus sequences in lieu of the homologous GBV-B sequence, providing unique tools for drug discovery efforts. A full-length molecular clone of GBV-B was constructed, as described in later sections of this specification.

GBV-B can be used as a model for HCV, and the GBV-B genome can be used as the acceptor molecule in the construction of chimeric viral RNAs containing sequences of both HCV and GBV-B. Such studies will allow one to investigate the mechanisms for the different biological properties of these viruses and to discover and investigate potential inhibitors of specific HCV activities (*e.g.*, proteinase) required for HCV replication. However, all this work is dependent upon construction of an infectious clone of GBV-B, which is itself dependent on the incorporation of the correct 3' terminal nucleotide sequence within this clone. GBV-B has unique advantages over HCV in terms of its ability to replicate and cause liver disease in tamarins, which present fewer restrictions to research than chimpanzees, the only nonhuman primate species known to be permissive for HCV.

An infectious molecular clone of GBV-B is expected to have utility in liver-specific gene expression or in gene therapy. This application might be enhanced by the inclusion of HCV genomic sequence in the form of a GBV-B/HCV chimera. Further, an infectious GBV-B/HCV chimera expressing HCV envelope proteins can have utility as a vaccine immunogen for hepatitis C.

A full-length cDNA copy of the GBV-B genome was constructed to contain the newly identified 3' terminal sequences. RNA transcribed from this cDNA copy of the genome would be infectious when inoculated into the liver of a GBV-B permissive tamarin, giving rise to rescued GBV-B virus particles. A chimeric molecule would then be constructed from this infectious GBV-B clone in which the HCV NS3 proteinase or proteinase/helicase sequence (or other relevant HCV sequences of interest in drug discovery efforts) would be placed in frame in lieu of the homologous GBV-B sequence, and this chimeric cDNA would be used to generate infectious GBV-B/HCV chimeric viruses by intrahepatic inoculation of synthetic RNA in tamarins. Published studies indicate that the GBV-B and HCV proteinases have closely related substrate recognition and cleavage properties, making such chimeras highly likely to be viable. These newly

generated chimeric GBV-B/HCV viruses could be used in preclinical testing of candidate HCV NS3 proteinase inhibitors.

Therefore, the present invention encompasses an isolated polynucleotide encoding  
5 a 3' sequence of the GBV-B genome. The polynucleotide may include the sequence  
identified as SEQ ID NO:1. It is contemplated that the polynucleotide may be a DNA  
molecule or it can be an RNA molecule. It is further contemplated that expression  
constructs may contain a polynucleotide that has a stretch of contiguous nucleotides from  
10 SEQ ID NO:1 and/or SEQ ID NO:2, for example, lengths of 50, 100, 150, 250, 500,  
1000, 5000, as well as the entire length of SEQ ID NO:1 or 2, are considered appropriate.  
Such polynucleotides may also be contained in other constructs of the invention or be  
used in the methods of the invention. Polynucleotides employing sequences from SEQ  
ID NO:1 may alternatively contain sequences from SEQ ID NO:2 in the constructs and  
methods of the present invention.

15 The invention is also understood as covering a viral expression construct that  
includes a polynucleotide encoding a 3' sequence of the GBV-B genome. This  
expression construct is further understood to contain the sequence identified as SEQ ID  
NO:1. The present invention contemplates the expression construct as a plasmid or as a  
20 virus. Furthermore, the expression construct can express GBV-B sequences; alternatively  
it may express sequences from a chimeric GBV-B/HCV virus.

The identification and isolation of a 3' sequence of GBV-B additionally provides  
a method of producing a virus, particularly a full-length virus, by introducing into a host  
25 cell a viral expression construct containing a polynucleotide encoding a 3' sequence of  
GBV-B and by culturing the host cell under conditions permitting production of a virus  
from the construct. This method can be practiced using a prokaryotic cell as a host cell,  
or by using a eukaryotic cell as a host cell. Furthermore, the eukaryotic cell can be  
located within an animal.

30

A method of producing virus according to the claimed invention can also be employed using a polynucleotide that contains synthetic RNA and/or synthetic DNA. Moreover, a step can be added to the method by also isolating any virus produced from the host cell. The virus can then be purified to homogeneity.

5

In further embodiments, the present invention encompasses an oligonucleotide between about 10 and about 259 consecutive bases of SEQ ID NO:1. This oligonucleotide is contemplated to be about 15 bases in length, about 20 bases in length, about 25 bases in length, about 30 bases in length, about 35 bases in length, about 50 bases in length, about 100 bases in length, about 150 bases in length, about 200 bases in length, or about 259 bases in length.

Additional examples of the claimed invention include a method for identifying a compound active against a viral infection by providing a virus expressed from a viral construct containing a 3' sequence of a GBV-B virus, by contacting the virus with a candidate substance; and by comparing the infectious ability of the virus in the presence of the candidate substance with the infectious ability of the virus in a similar system in the absence of the candidate substance. It is contemplated that the invention can be practiced using GBV-B virus or a GBV-B/HCV chimera.

20

The present invention can also be understood to provide a compound active against a viral infection identified by providing a virus expressed from a viral construct containing a 3' sequence of a GBV-B virus; contacting the virus with a candidate substance; and comparing the infectious ability of the virus in the presence of the candidate substance with the infectious ability of the virus in a similar system in the absence of the candidate substance. In some embodiments an active compound is identified using a GBV-B virus, while in other embodiments an active compound is identified using a GBV-B/HCV chimera.

25

As used herein the specification, "a" or "an" may mean one or more. As used herein in the claim(s), when used in conjunction with the word "comprising," the words "a" or "an" may mean one or more than one. As used herein "another" may mean at least a second or more.

5

Other objects, features and advantages of the present invention will become apparent from the following detailed description. It should be understood, however, that the detailed description and the specific examples, while indicating preferred embodiments of the invention, are given by way of illustration only, since various changes and modifications within the spirit and scope of the invention will become apparent to those skilled in the art from this detailed description.

### **BRIEF DESCRIPTION OF THE DRAWINGS**

The following drawings form part of the present specification and are included to further demonstrate certain aspects of the present invention. The invention may be better understood by reference to one or more of these drawings in combination with the detailed description of specific embodiments presented herein.

**FIG. 1.** Predicted secondary RNA structure at the 3' end of the novel 3' GBV-B sequence. The structure shown is that predicted for the 3' terminal 108 nucleotides of the GBV-B genomic RNA by the MFOLD 3.0 computer program of Zucker and Turner, and has an initial free energy of -48 kcal/mole. The predicted structure contains 3 stem-loops, numbered from the 3' end of the genome and labeled SL-1, SL-2, and SL-3. The structure of SL-1 is highly probable, given its terminal position within the genome. Alternative foldings of SL-2 and SL-3 are possible.

## DESCRIPTION OF ILLUSTRATIVE EMBODIMENTS

### **A. GBV-B Virus**

The GBV-B genome structure is very similar to hepatitis C and these viruses share approximately 25% nucleotide identity (Simons *et al.*, 1995; Muerhoff *et al.*, 1995).

- 5 As indicated above, this makes GBV-B more closely related to HCV than any other known virus. GBV-B genomic RNA is about 9.5 kb in length (Muerhoff *et al.*, 1995) with a structured 5' noncoding region that contains an IRES that shares many structural features with the HCV IRES (Honda *et al.*, 1996; Rijnbrand *et al.*, 1999). As in HCV, this IRES drives the cap-independent translation of a long open reading frame. The
- 10 polyprotein expressed from this reading frame appears to be organized identically to that of HCV, and processed to generate proteins with functions similar to those of HCV (Muerhoff *et al.*, 1995). In fact, the major serine proteinases of these viruses (NS3) have been shown to have similar cleavage specificities (Scarselli *et al.*, 1997). Finally, like HCV and distinct from the pestiviruses, the genomic RNA of GBV-B has a poly(U) tract
- 15 located near its 3' terminus (Simons *et al.*, 1995; Muerhoff *et al.*, 1995). In addition, unreported sequences located at the extreme 3' end of the genome have been identified. This work indicates that the GBV-B RNA, like that of HCV (HCV (Tanaka *et al.*, 1995; Kolykhalov *et al.*, 1996), terminates in a lengthy run of heterogeneous bases (310 nts in GBV-B) possessing a readily apparent secondary structure

### **20 B. Nucleic Acids**

The present invention provides a nucleic acid sequence encoding a 3' sequence of the GBV-B genome (SEQ ID NO:1).

- 25 It should be clear that the present invention is not limited to the specific nucleic acids disclosed herein. As discussed below, a "3' sequence of the GBV-B genome" may contain a variety of different bases and yet still be functionally indistinguishable from the sequences disclosed herein. Such functionally indistinguishable sequences are likely to

maintain the basic structure depicted in FIGs. 1 and 2, which may be used to guide the prediction of viable nucleotide substitutions.

### 1. Polynucleotides Encoding the 3' Sequence of the GBV-B Genome

5 A 3' sequence of the GBV-B genome disclosed in SEQ ID NO:1 is one aspect of the present invention. Nucleic acids according to the present invention may encode the 3' sequence of the GBV-B genome set forth in SEQ ID NO:1, the entire GBV-B genome, or any other fragment of a 3' sequence of the GBV-B genome set forth herein. The nucleic acid may be derived from genomic RNA as cDNA, *i.e.*, cloned directly from the genome of GBV-B. cDNA may also be assembled from synthetic oligonucleotide segments.

10

It also is contemplated that a 3' sequence of the GBV-B genome may be represented by natural variants that have slightly different nucleic acid sequences but, nonetheless, maintain the same general structure (see FIGs. 1 and 2) and perform the same function in RNA replication.

15

As used in this application, the term "a nucleic acid encoding a 3' sequence of the GBV-B genome" refers to a nucleic acid molecule that may be isolated free of total viral nucleic acid. In preferred embodiments, the invention concerns nucleic acid sequences essentially as set forth in SEQ ID NO:1, SEQ ID NO:2, SEQ ID NO:3, SEQ ID NO:4, 20 SEQ ID NO:5, SEQ ID NO:6, SEQ ID NO:7, SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, and SEQ ID NO:12. The term "as set forth in SEQ ID NO:1" means that the nucleic acid sequence substantially corresponds to a portion of SEQ ID NO:1. It is contemplated that the techniques and methods described in this disclosure may apply to any of the sequences contained herein, including SEQ ID NO:1, SEQ ID NO:2, 25 SEQ ID NO:3, SEQ ID NO:4, SEQ ID NO:5, SEQ ID NO:6, SEQ ID NO:7, SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, and SEQ ID NO:12.

Allowing for the degeneracy of the genetic code, sequences that have at least about 50%, usually at least about 60%, more usually about 70%, most usually about 80%,

preferably at least about 90% and most preferably about 95% of nucleotides that are identical to the nucleotides of SEQ ID NO:1 will be sequences that are "as set forth in SEQ ID NO:1." Sequences that are essentially the same as those set forth in SEQ ID NO:1 may also be functionally defined as sequences that are capable of hybridizing to a nucleic acid segment containing the complement of SEQ ID NO:1 under standard conditions.

The nucleic acid segments and polynucleotides of the present invention include those encoding biologically functional equivalent 3' sequences of the GBV-B genome. Changes designed by man may be introduced through the application of site-directed mutagenesis techniques or may be introduced randomly and screened later for the desired function, as described below.

3' sequence of the GBV-B genome sequences also are provided. Each of the foregoing is included within all aspects of the following description. The present invention concerns cDNA segments reverse transcribed from GBV-B genomic RNA (referred to as "DNA"). As used herein, the term "polynucleotide" refers to an RNA or DNA molecule that may be isolated free of other RNA or DNA of a particular species.

"Isolated substantially away from other coding sequences" means that the 3' sequence of the GBV-B genome forms the significant part of the RNA or DNA segment and that the segment does not contain large portions of naturally-occurring coding RNA or DNA, such as large fragments or other functional genes or cDNA noncoding regions. Of course, this refers to the polynucleotide as originally isolated, and does not exclude genes or coding regions later added to the it by the hand of man.

In certain other embodiments, the invention concerns isolated DNA segments (cDNA segments reverse transcribed from GVB-B genomic RNA) and recombinant vectors that include within their sequence a nucleic acid sequence essentially as set forth in SEQ ID NO:1. The term "essentially as set forth in SEQ ID NO:1" is used in the same sense as described above.

It also will be understood that nucleic acid sequences may include additional residues, such as additional 5' or 3' sequences, and still be essentially as set forth in one of the sequences disclosed herein, so long as the sequence meets the criteria set forth above, including the maintenance of biological activity. The addition of terminal sequences particularly applies to nucleic acid sequences that may, for example, include additional various non-coding sequences flanking either of the 5' or 3' portions of the coding region, which are known to occur within viral genomes.

Sequences that are essentially the same as those set forth in SEQ ID NO:1 also may be functionally defined as sequences that are capable of hybridizing to a nucleic acid segment containing the complement of SEQ ID NO:1 under relatively stringent conditions. Suitable relatively stringent hybridization conditions will be well known to those of skill in the art.

The nucleic acid segments of the present invention, regardless of the length of the coding sequence itself, may be combined with other RNA or DNA sequences, such as promoters, polyadenylation signals, additional restriction enzyme sites, multiple cloning sites, other coding segments, and the like, such that their overall length may vary considerably. It is therefore contemplated that a nucleic acid fragment of almost any length may be employed, with the total length preferably being limited by the ease of preparation and use in the intended recombinant DNA protocol.

For example, nucleic acid fragments may be prepared that include a short contiguous stretch identical to or complementary to SEQ ID NO:1, such as about 15-24 or about 25-34 nucleotides and that are up to about 259 nucleotides being preferred in certain cases. Other stretches of contiguous sequence that may be identical or complementary to any of the sequences disclosed herein, including the SEQ ID NOS. include the following ranges of nucleotides: 50-9,399, 100-9,000, 150-8,000, 200-7,000, 250-6,000, 300-5,000, 350-4,000, 400-3,000, 450-2,000, 500-1000. RNA and DNA

segments with total lengths of about 1,000, about 500, about 200, about 100 and about 50 base pairs in length (including all intermediate lengths) are also contemplated to be useful.

5           In a non-limiting example, one or more nucleic acid constructs may be prepared that include a contiguous stretch of nucleotides identical to or complementary to SEQ ID NO:1, SEQ ID NO:2, SEQ ID NO:3, SEQ ID NO:4, SEQ ID NO:5, SEQ ID NO:6, SEQ ID NO:7, SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, or SEQ ID NO:12. Such a stretch of nucleotides, or a nucleic acid construct, may be about, or at  
10   least about, 3, about 4, about 5, about 6, about 7, about 8,, about 9, about 10, about 11, about 12, about 13, about 14, about 15, about 16, about 17, about 18, about 19, about 20, about 21, about 22, about 23, about 24, about 25, about 26, about 27, about 28, about 29, about 30, about 31, about 32, about 33, about 34, about 35, about 36, about 37, about 38, about 39 about 40, about 45, about 50, about 55, about 60, about 65, about 70, about 75,  
15   about 80, about 85, about 90, about 95, about 100, about 105, about 110, about 115, about 120, about 125, about 130, about 135, about 140, about 145, about 150, about 155, about 160, about 165, about 170, about 175, about 180, about 185, about 190, about 195, about 200, about 210, about 220, about 230, about 240, about 250, about 260, about 270, about 280, about 290, about 300, about 310, about 320, about 330, about 340, about 350, about  
20   360, about 370, about 380, about 390, about 400, about 410, about 420, about 430, about 440, about 450, about 460, about 470, about 480, about 490, about 500, about 510, about 520, about 530, about 540, about 550, about 560, about 570, about 580, about 590, about 600, about 610, about 618, about 650, about 700, about 750, about 1,000, about 2,000, about 3,000, about 4,000, about 5,000, about 6,000, about 7,000, about 8,000, about  
25   9,000, about 9,100, about 9,200, about 9,300, about 9,399, about 9,400, about 9,500, about 9,600, about 9,700, about 9,800, about 9,900, about 10,000, about 15,000, about 20,000, about 30,000, about 50,000, about 100,000, about 250,000, about 500,000, about 750,000, to about 1,000,000 nucleotides in length, as well as constructs of greater size, up to and including chromosomal sizes (including all intermediate lengths and intermediate

ranges), given the advent of nucleic acids constructs such as a yeast artificial chromosome are known to those of ordinary skill in the art.

It will be readily understood that "intermediate lengths," in these contexts means any length between the quoted ranges, such as 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, etc.; 100, 101, 102, 103, etc.; 150, 151, 152, 153, etc.; including all integers through the 200-500; 500-1,000; 1,000-2,000; ranges, up to and including sequences of about 1,001, 1,250, 1,500, and the like.

The various probes and primers designed around the disclosed nucleotide sequences of the present invention may be of any length. By assigning numeric values to a sequence, for example, the first residue is 1, the second residue is 2, *etc.*, an algorithm defining all primers can be proposed:

$$n \text{ to } n + y$$

where  $n$  is an integer from 1 to the last number of the sequence and  $y$  is the length of the primer minus one, where  $n + y$  does not exceed the last number of the sequence. Thus, for a 20-mer, the probes correspond to bases 1 to 20, 2 to 21, 3 to 22 ... and so on. For a 30-mer, the probes correspond to bases 1 to 30, 2 to 31, 3 to 32 ... and so on. For a 35-mer, the probes correspond to bases 1 to 35, 2 to 36, 3 to 37 ... and so on.

## 2. Oligonucleotide Probes and Primers

Naturally, the present invention also encompasses RNA and DNA segments that are complementary, or essentially complementary, to the sequence set forth in SEQ ID NO:1. Nucleic acid sequences that are "complementary" are those that are capable of base-pairing according to the standard Watson-Crick complementary rules. As used herein, the term "complementary sequences" means nucleic acid sequences that are substantially complementary, as may be assessed by the same nucleotide comparison set forth above, or as defined as being capable of hybridizing to the nucleic acid segment of SEQ ID NO. 1 under relatively stringent conditions such as those described herein. Such sequences may

encode the entire 3' sequence of the GBV-B genome or functional or non-functional fragments thereof.

Alternatively, the hybridizing segments may be shorter oligonucleotides. Sequences of 17 bases long should occur only once in the human genome and, therefore, suffice to specify a unique target sequence. Although shorter oligomers are easier to make and increase *in vivo* accessibility, numerous other factors are involved in determining the specificity of hybridization. Both binding affinity and sequence specificity of an oligonucleotide to its complementary target increases with increasing length. It is contemplated that exemplary oligonucleotides of 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 25, 30, 35, 40, 45, 50, 55, 60, 65, 70, 75, 80, 85, 90, 95, 100, 125, 150, 175, 200, 225 or more base pairs will be used, although others are contemplated. Longer polynucleotides encoding 250, 500, 1000, 1212, 1500, 2000, 2500, 3000 or 3431 bases and longer are contemplated as well. Such oligonucleotides will find use, for example, as probes in Southern and Northern blots and as primers in amplification reactions.

Suitable hybridization conditions will be well known to those of skill in the art. In certain applications, for example, substitution of amino acids by site-directed mutagenesis, it is appreciated that lower stringency conditions are required. Under these conditions, hybridization may occur even though the sequences of probe and target strand are not perfectly complementary but are mismatched at one or more positions. Conditions may be rendered less stringent by increasing salt concentration and decreasing temperature. For example, a medium stringency condition could be provided by about 0.1 to 0.25 M NaCl at temperatures of about 37°C to about 55°C, while a low stringency condition could be provided by about 0.15 M to about 0.9 M salt, at temperatures ranging from about 20°C to about 55°C. Thus, hybridization conditions can be readily manipulated and thus will generally be a method of choice depending on the desired results.

In other embodiments, hybridization may be achieved under conditions of, for example, 50 mM Tris-HCl (pH 8.3), 75 mM KCl, 3 mM MgCl<sub>2</sub>, 10 mM dithiothreitol, at

temperatures between approximately 20°C to about 37°C. Other hybridization conditions utilized could include approximately 10 mM Tris-HCl (pH 8.3), 50 mM KCl, 1.5 mM MgCl<sub>2</sub>, at temperatures ranging from approximately 40°C to about 72°C. Formamide and SDS also may be used to alter the hybridization conditions.

5

One method of using probes and primers of the present invention is in the search for other viral sequences related to GBV-B or, more particularly, homologs of the GBV-B sequence. By varying the stringency of hybridization, and the region of the probe, different degrees of homology may be discovered.

10

Another way of exploiting probes and primers of the present invention is in site-directed, or site-specific, mutagenesis. The technique provides a ready ability to prepare and test sequence variants, incorporating one or more of the foregoing considerations, by introducing one or more nucleotide sequence changes into complementary DNA. Site-specific mutagenesis allows the production of mutants through the use of specific oligonucleotide sequences that encode the DNA sequence of the desired mutation, as well as a sufficient number of adjacent nucleotides, to provide a primer sequence of sufficient size and sequence complexity to form a stable duplex on both sides of the deletion junction being traversed. Typically, a primer of about 17 to 25 nucleotides in length is preferred, with about 5 to 10 residues on both sides of the junction of the sequence being altered.

15

20

The technique typically employs a bacteriophage vector that exists in both a single stranded and double stranded form. Typical vectors useful in site-directed mutagenesis include vectors such as the M13 phage. These phage vectors are commercially available and their use is generally well known to those skilled in the art. Double stranded plasmids are also routinely employed in site directed mutagenesis, which eliminates the step of transferring the gene of interest from a phage to a plasmid.

25

005090-05070500

In general, site-directed mutagenesis is performed by first obtaining a single-stranded vector, or melting of two strands of a double stranded vector which includes within its sequence a DNA sequence encoding the desired protein. An oligonucleotide primer bearing the desired mutated sequence is synthetically prepared. This primer is then  
5 annealed with the single-stranded DNA preparation, taking into account the degree of mismatch when selecting hybridization conditions, and subjected to DNA polymerizing enzymes such as *E. coli* polymerase I Klenow fragment, in order to complete the synthesis of the mutation-bearing strand. Thus, a heteroduplex is formed wherein one strand encodes the original non-mutated sequence and the second strand bears the desired  
10 mutation. This heteroduplex vector is then used to transform appropriate cells, such as *E. coli* cells, and clones are selected that include recombinant vectors bearing the mutated sequence arrangement. There are newer and simpler site-directed mutagenesis techniques that can also be employed for this purpose. These include procedures marketed in kit form that are readily available to one of ordinary skill in the art.

15

The preparation of sequence variants of the selected gene using site-directed mutagenesis is provided as a means of producing potentially useful species and is not meant to be limiting, as there are other ways in which sequence variants of genes may be obtained. For example, recombinant vectors encoding the desired gene may be treated  
20 with mutagenic agents, such as hydroxylamine, to obtain sequence variants.

### 3. Antisense Constructs

In certain embodiments of the invention, the use of antisense constructs of the 3' sequence of the GBV-B genome is contemplated.

25

Antisense methodology takes advantage of the fact that nucleic acids tend to pair with "complementary" sequences. By complementary, it is meant that polynucleotides are those which are capable of base-pairing according to the standard Watson-Crick complementarity rules. That is, the larger purines will base pair with the smaller pyrimidines to form combinations of guanine paired with cytosine (G:C) and adenine

paired with either thymine (A:T) in the case of DNA, or adenine paired with uracil (A:U) in the case of RNA. Inclusion of less common bases such as inosine, 5-methylcytosine, 6-methyladenine, hypoxanthine and others in hybridizing sequences does not interfere with pairing.

5

Targeting double-stranded (ds) DNA with polynucleotides leads to triple-helix formation; targeting RNA will lead to double-helix formation. Antisense polynucleotides, when introduced into a target cell, specifically bind to their target polynucleotide and interfere with transcription, RNA processing, transport, translation and/or stability. Antisense RNA constructs, or DNA encoding such antisense RNAs, may be employed to inhibit gene transcription or translation or both within a host cell, either *in vitro* or *in vivo*, such as within a host animal, including a human subject.

Antisense constructs could be used to block early steps in the replication of GBV-B and related viruses, by annealing to 3' terminal sequences and blocking their role in negative-strand initiation.

As stated above, "complementary" or "antisense" means polynucleotide sequences that are substantially complementary over their entire length and have very few base mismatches. For example, sequences of 15 bases in length may be termed complementary when they have complementary nucleotides at 13 or 14 positions. Naturally, sequences which are completely complementary will be sequences which are entirely complementary throughout their entire length and have no base mismatches. Other sequences with lower degrees of homology also are contemplated. For example, an antisense construct which has limited regions of high homology but also contains a non-homologous region (*e.g.*, ribozyme; see below) could be designed. These molecules, though having less than 50% homology, would bind to target sequences under appropriate conditions.

#### 4. Amplification and PCR™

5 The present invention utilizes amplification techniques in a number of its  
embodiments. Nucleic acids used as a template for amplification are isolated from cells  
contained in the biological sample, according to standard methodologies (Sambrook  
*et al.*, 1989). The nucleic acid may be genomic DNA or RNA or fractionated or whole  
cell RNA. Where RNA is used, it may be desired to convert the RNA to a  
complementary DNA using reverse transcriptase (RT). In one embodiment, the RNA is  
genomic RNA and is used directly as the template for amplification. In others, genomic  
RNA is first converted to a complementary DNA sequence (cDNA) and this product is  
10 amplified according to protocols described below.

15 Pairs of primers that selectively hybridize to nucleic acids corresponding to GBV-  
B sequences are contacted with the isolated nucleic acid under conditions that permit  
selective hybridization. The term “primer,” as defined herein, is meant to encompass any  
nucleic acid that is capable of priming the synthesis of a nascent nucleic acid in a  
template-dependent process. Typically, primers are oligonucleotides from ten to twenty  
base pairs in length, but longer sequences can be employed. Primers may be provided in  
double-stranded or single-stranded form, although the single-stranded form is preferred.

20 Once hybridized, the nucleic acid:primer complex is contacted with one or more  
enzymes that facilitate template-dependent nucleic acid synthesis. Multiple rounds of  
amplification, also referred to as “cycles,” are conducted until a sufficient amount of  
amplification product is produced.

25 Next, the amplification product is detected. In certain applications, the detection  
may be performed by visual means. Alternatively, the detection may involve indirect  
identification of the product via chemiluminescence, radioactive scintigraphy of  
incorporated radiolabel or fluorescent label or even via a system using electrical or  
thermal impulse signals.

30

A number of template dependent processes are available to amplify the marker sequences present in a given template sample. One of the best known amplification methods is the polymerase chain reaction (referred to as PCR™) which is described in detail in U.S. Patent Nos. 4,683,195, 4,683,202 and 4,800,159, and each incorporated  
5 herein by reference in entirety.

Briefly, in PCR™, two or more primer sequences are prepared that are  
complementary to regions on opposite complementary strands of the marker sequence.

An excess of deoxynucleoside triphosphates are added to a reaction mixture along with a  
10 DNA polymerase, *e.g.*, *Taq* polymerase. If the marker sequence is present in a sample, the primers will bind to the marker and the polymerase will cause the primers to be extended along the marker sequence by adding on nucleotides. By raising and lowering the temperature of the reaction mixture, the extended primers will dissociate from the marker to form reaction products, excess primers will bind to the marker and to the  
15 reaction products and the process is repeated.

A reverse transcriptase PCR™ amplification procedure may be performed in order to quantify the amount of mRNA amplified. Methods of reverse transcribing RNA into cDNA are well known and described in Sambrook *et al.*, 1989. Alternative methods for  
20 reverse transcription utilize thermostable, RNA-dependent DNA polymerases. These methods are described in WO 90/07641, filed December 21, 1990, incorporated herein by reference. Polymerase chain reaction methodologies are well known in the art.

Another method for amplification is the ligase chain reaction ("LCR"), disclosed  
25 in EPA No. 320 308, incorporated herein by reference in its entirety. U.S. Patent 4,883,750 describes a method similar to LCR for binding probe pairs to a target sequence.

Qbeta Replicase, described in PCT Application No. PCT/US87/00880, incorporated herein by reference, also may be used as still another amplification method  
30 in the present invention.

An isothermal amplification method, in which restriction endonucleases and ligases are used to achieve the amplification of target molecules that contain nucleotide 5'-[alpha-thio]-triphosphates in one strand of a restriction site also may be useful in the  
5 amplification of nucleic acids in the present invention.

Strand Displacement Amplification (SDA) is another method of carrying out isothermal amplification of nucleic acids which involves multiple rounds of strand displacement and synthesis, *i.e.*, nick translation. A similar method, called Repair Chain  
10 Reaction (RCR), involves annealing several probes throughout a region targeted for amplification, followed by a repair reaction in which only two of the four bases are present. The other two bases can be added as biotinylated derivatives for easy detection. A similar approach is used in SDA. Target specific sequences also can be detected using a cyclic probe reaction (CPR). In CPR, a probe having 3' and 5' sequences of  
15 non-specific DNA and a middle sequence of specific RNA is hybridized to DNA that is present in a sample. Upon hybridization, the reaction is treated with RNase H, and the products of the probe identified as distinctive products that are released after digestion. The original template is annealed to another cycling probe and the reaction is repeated.

20 Still another amplification methods described in GB Application No. 2 202 328, and in PCT Application No. PCT/US89/01025, each of which is incorporated herein by reference in its entirety, may be used in accordance with the present invention. In the former application, "modified" primers are used in a PCR-like, template- and enzyme-dependent synthesis. The primers may be modified by labeling with a capture  
25 moiety (*e.g.*, biotin) and/or a detector moiety (*e.g.*, enzyme). In the latter application, an excess of labeled probes are added to a sample. In the presence of the target sequence, the probe binds and is cleaved catalytically. After cleavage, the target sequence is released intact to be bound by excess probe. Cleavage of the labeled probe signals the presence of the target sequence.

30

Other nucleic acid amplification procedures include transcription-based amplification systems (TAS), including nucleic acid sequence based amplification (NASBA) and 3SR Gingeras *et al.*, PCT Application WO 88/10315, incorporated herein by reference.

5

Davey *et al.*, EPA No. 329 822 (incorporated herein by reference in its entirety) disclose a nucleic acid amplification process involving cyclically synthesizing single-stranded RNA ("ssRNA"), ssDNA, and double-stranded DNA (dsDNA), which may be used in accordance with the present invention.

10

Miller *et al.*, PCT Application WO 89/06700 (incorporated herein by reference in its entirety) disclose a nucleic acid sequence amplification scheme based on the hybridization of a promoter/primer sequence to a target ssDNA followed by transcription of many RNA copies of the sequence. This scheme is not cyclic, *i.e.*, new templates are not produced from the resultant RNA transcripts. Other amplification methods include "RACE" and "one-sided PCR" (Frohman, 1990 incorporated by reference).

15

Methods based on ligation of two (or more) oligonucleotides in the presence of nucleic acid having the sequence of the resulting "di-oligonucleotide", thereby amplifying the di-oligonucleotide, also may be used in the amplification step of the present invention.

20

Following any amplification, it may be desirable to separate the amplification product from the template and the excess primer for the purpose of determining whether specific amplification has occurred. In one embodiment, amplification products are separated by agarose, agarose-acrylamide or polyacrylamide gel electrophoresis using standard methods. *See* Sambrook *et al.*, 1989.

25

Alternatively, chromatographic techniques may be employed to effect separation. There are many kinds of chromatography that may be used in the present invention:

30

adsorption, partition, ion-exchange and molecular sieve, and many specialized techniques for using them including column, paper, thin-layer and gas chromatography.

Amplification products must be visualized in order to confirm amplification of the  
5 marker sequences. One typical visualization method involves staining of a gel with ethidium bromide and visualization under UV light. Alternatively, if the amplification products are integrally labeled with radio- or fluorometrically-labeled nucleotides, the amplification products can then be exposed to x-ray film or visualized under the appropriate stimulating spectra, following separation.

10

In one embodiment, visualization is achieved indirectly. Following separation of amplification products, a labeled nucleic acid probe is brought into contact with the amplified marker sequence. The probe preferably is conjugated to a chromophore but may be radiolabeled. In another embodiment, the probe is conjugated to a binding  
15 partner, such as an antibody or biotin, and the other member of the binding pair carries a detectable moiety.

In one embodiment, detection is by Southern blotting and hybridization with a labeled probe. The techniques involved in Southern blotting are well known to those of skill in the art and can be found in many standard books on molecular protocols. See  
20 Sambrook *et al.*, 1989. Briefly, amplification products are separated by gel electrophoresis. The gel is then contacted with a membrane, such as nitrocellulose or nylon, permitting transfer of the nucleic acid and non-covalent binding. Subsequently, the membrane is incubated with a chromophore-conjugated probe that is capable of  
25 hybridizing with a target amplification product. Detection is by exposure of the membrane to x-ray film or ion-emitting detection devices.

One example of the foregoing is described in U.S. Patent 5,279,721, incorporated by reference herein, which discloses an apparatus and method for the automated  
30 electrophoresis and transfer of nucleic acids. The apparatus permits electrophoresis and

blotting without external manipulation of the gel and is ideally suited to carrying out methods according to the present invention.

## 5. Expression Constructs

5 In some embodiments of the present invention, an expression construct that encodes a 3' sequence of GBV-B is utilized. The term "expression construct" is meant to include any type of genetic construct containing a nucleic acid coding for a gene product in which part or all of the nucleic acid encoding sequence is capable of being transcribed. The transcript may be translated into a protein, but it need not be. Expression includes  
10 both transcription of a gene and translation of mRNA into a gene product. Expression may also include only transcription of the nucleic acid encoding a gene of interest.

In some constructs, the nucleic acid encoding a gene product is under transcriptional control of promoter and/or enhancer. The term promoter will be used here  
15 to refer to a group of transcriptional control modules that are clustered around the initiation site for RNA polymerase II. Much of the thinking about how promoters are organized derives from analyses of several viral promoters, including those for the HSV thymidine kinase (tk) and SV40 early transcription units. These studies have shown that promoters are composed of discrete functional modules, each consisting of approximately  
20 7-20 bp of nucleic acids, and containing one or more recognition sites for transcriptional activator or repressor proteins.

At least one module in each promoter functions to position the start site for RNA synthesis. The best known example of this is the TATA box, but in some promoters  
25 lacking a TATA box, such as the promoter for the mammalian terminal deoxynucleotidyl transferase gene and the promoter for the SV40 late genes, a discrete element overlying the start site itself helps to fix the place of initiation.

Additional promoter elements regulate the frequency of transcriptional initiation.  
30 Typically, these are located in the region 30-110 bp upstream of the start site, although a

number of promoters have recently been shown to contain functional elements downstream of the start site as well. The spacing between promoter elements frequently is flexible, so that promoter function is preserved when elements are inverted or moved relative to one another. In the tk promoter, the spacing between promoter elements can be increased to 50 bp apart before activity begins to decline. Depending on the promoter, it appears that individual elements can function either co-operatively or independently to activate transcription.

Enhancers were originally detected as genetic elements that increased transcription from a promoter located at a distant position on the same molecule of DNA. This ability to act over a large distance had little precedent in classic studies of prokaryotic transcriptional regulation. Subsequent work showed that regions of nucleic acids with enhancer activity are organized much like promoters. That is, they are composed of many individual elements, each of which binds to one or more transcriptional proteins.

The basic distinction between enhancers and promoters is operational. An enhancer region as a whole must be able to stimulate transcription at a distance; this need not be true of a promoter region or its component elements. On the other hand, a promoter must have one or more elements that direct initiation of RNA synthesis at a particular site and in a particular orientation, whereas enhancers lack these specificities. Promoters and enhancers are often overlapping and contiguous, often seeming to have a very similar modular organization.

## **6. Host Cells and Permissive Cells**

As used herein, the terms "cell," "cell line," and "cell culture" may be used interchangeably. All of these terms also include their progeny, which is any and all subsequent generations. It is understood that all progeny may not be identical due to deliberate or inadvertent mutations. In the context of the present invention, "host cell" refers to a prokaryotic or eukaryotic cell, and it includes any transformable organisms that

is capable of replicating a vector or virus and/or expressing viral proteins. A host cell can, and has been, used as a recipient for vectors, including viral vectors. A host cell may be “transfected” or “transformed,” which refers to a process by which exogenous nucleic acid is transferred or introduced into the host cell. A transformed cell includes the primary subject cell and its progeny. A “permissive cell” refers to a cell that supports the replication of a given virus and consequently undergoes cell lysis. In the context of the present invention, such a virus would include HCV, GBV-B, or other hepatitis viruses. In a “nonpermissive cell,” productive infection does not result, but the cell may become stably transformed. In some embodiments, methods employ permissive cells that are a cell line derived from liver cells (liver cell line).

Host cells may be derived from prokaryotes or eukaryotes, depending upon whether the desired result is replication of the vector or expression of part or all of the vector-encoded nucleic acid sequences. Numerous cell lines and cultures are available for use as a host cell, and they can be obtained through the American Type Culture Collection (ATCC), which is an organization that serves as an archive for living cultures and genetic materials ([www.atcc.org](http://www.atcc.org)). An appropriate host can be determined by one of skill in the art based on the vector backbone and the desired result. A plasmid or cosmid, for example, can be introduced into a prokaryote host cell for replication of many vectors. Bacterial cells used as host cells for vector replication and/or expression include DH5 $\alpha$ , JM109, and KC8, as well as a number of commercially available bacterial hosts such as SURE<sup>®</sup> Competent Cells and SOLOPACK<sup>™</sup> Gold Cells (STRATAGENE<sup>®</sup>, La Jolla). Alternatively, bacterial cells such as *E. coli* LE392 could be used as host cells for phage viruses.

Examples of eukaryotic host cells for replication and/or expression of a vector include HeLa, NIH3T3, Jurkat, 293, Cos, CHO, Saos, and PC12. Many host cells from various cell types and organisms are available and would be known to one of skill in the art. Similarly, a viral vector or virus or virus particle may be used in conjunction with either a eukaryotic or prokaryotic host cell, particularly one that is permissive for

replication or expression of the vector. It is contemplated that the present invention includes vectors composed of viral sequences, viruses, and viral particles in the methods of the present invention, and that they may be used interchangeably in these methods, depending on their utility.

5

Some vectors may employ control sequences that allow it to be replicated and/or expressed in both prokaryotic and eukaryotic cells. One of skill in the art would further understand the conditions under which to incubate all of the above described host cells to maintain them and to permit replication of a vector. Also understood and known are techniques and conditions that would allow large-scale production of vectors, as well as production of the nucleic acids encoded by vectors and their cognate polypeptides, proteins, or peptides.

10

## **7. Pharmaceutical Compositions**

15

The present invention encompasses the use of a 3' sequence of GBV-B in the production of or use as a vaccine to combat HCV infection. Compositions of the present invention comprise an effective amount of GBV-B clone as a therapeutic dissolved or dispersed in a pharmaceutically acceptable carrier or aqueous medium. The phrases "pharmaceutically or pharmacologically acceptable" refer to molecular entities and compositions that do not produce an adverse, allergic or other untoward reaction when administered to an animal, or a human, as appropriate.

20

As used herein, "pharmaceutically acceptable carrier" includes any and all solvents, dispersion media, coatings, antibacterial and antifungal agents, isotonic and absorption delaying agents and the like. The use of such media and agents for pharmaceutical active substances is well known in the art. Except insofar as any conventional media or agent is incompatible with the active ingredient, its use in the therapeutic compositions is contemplated. Supplementary active ingredients can also be incorporated into the compositions. For human administration, preparations should meet

25

sterility, pyrogenicity, general safety and purity standards as required by FDA Office of Biologics standards.

5 The biological material should be extensively dialyzed to remove undesired small molecular weight molecules and/or lyophilized for more ready formulation into a desired vehicle, where appropriate. The active compounds will then generally be formulated for parenteral administration, *e.g.*, formulated for injection via the intravenous, intramuscular, sub-cutaneous, intralesional, or even intraperitoneal routes. The preparation of an aqueous composition that contains GVB-B nucleic acid sequences as an  
10 active component or ingredient will be known to those of skill in the art in light of the present disclosure. Typically, such compositions can be prepared as injectables, either as liquid solutions or suspensions; solid forms suitable for using to prepare solutions or suspensions upon the addition of a liquid prior to injection can also be prepared; and the preparations can also be emulsified.

15 The pharmaceutical forms suitable for injectable use include sterile aqueous solutions or dispersions; formulations including sesame oil, peanut oil or aqueous propylene glycol; and sterile powders for the extemporaneous preparation of sterile injectable solutions or dispersions. In all cases the form must be sterile and must be fluid  
20 to the extent that easy syringability exists. It must be stable under the conditions of manufacture and storage and must be preserved against the contaminating action of microorganisms, such as bacteria and fungi.

Solutions of the active compounds as free base or pharmacologically acceptable  
25 salts can be prepared in water suitably mixed with a surfactant, such as hydroxypropylcellulose. Dispersions can also be prepared in glycerol, liquid polyethylene glycols, and mixtures thereof and in oils. Under ordinary conditions of storage and use, these preparations contain a preservative to prevent the growth of microorganisms.

30

5 A GBV-B clone of the present invention can be formulated into a composition in a neutral or salt form. Pharmaceutically acceptable salts include the acid addition salts (formed with the free amino groups of the protein) and are formed with inorganic acids such as, for example, hydrochloric or phosphoric acids, or such organic acids as acetic, oxalic, tartaric, mandelic, and the like. Salts formed with the free carboxyl groups can also be derived from inorganic bases such as, for example, sodium, potassium, ammonium, calcium, or ferric hydroxides, and such organic bases as isopropylamine, trimethylamine, histidine, procaine and the like. In terms of using peptide therapeutics as active ingredients, the technology of U.S. Patents 4,608,251; 4,601,903; 4,599,231; 10 4,599,230; 4,596,792; and 4,578,770, each incorporated herein by reference, may be used.

15 The carrier also can be a solvent or dispersion medium containing, for example, water, ethanol, polyol (for example, glycerol, propylene glycol, and liquid polyethylene glycol, and the like), suitable mixtures thereof, and vegetable oils. The proper fluidity can be maintained, for example, by the use of a coating, such as lecithin, by the maintenance of the required particle size in the case of dispersion and by the use of surfactants. The prevention of the action of microorganisms can be brought about by various antibacterial and antifungal agents, for example, parabens, chlorobutanol, phenol, 20 sorbic acid, thimerosal, and the like. In many cases, it will be preferable to include isotonic agents, for example, sugars or sodium chloride. Prolonged absorption of the injectable compositions can be brought about by the use in the compositions of agents delaying absorption, for example, aluminum monostearate and gelatin.

25 Sterile injectable solutions are prepared by incorporating the active compounds in the required amount in the appropriate solvent with various of the other ingredients enumerated above, as required, followed by filtered sterilization. Generally, dispersions are prepared by incorporating the various sterilized active ingredients into a sterile vehicle which contains the basic dispersion medium and the required other ingredients 30 from those enumerated above. In the case of sterile powders for the preparation of sterile

injectable solutions, the preferred methods of preparation are vacuum-drying and freeze-drying techniques which yield a powder of the active ingredient plus any additional desired ingredient from a previously sterile-filtered solution thereof. The preparation of more, or highly, concentrated solutions for direct injection is also contemplated, where  
5 the use of DMSO as solvent is envisioned to result in extremely rapid penetration, delivering high concentrations of the active agents to a small area.

Upon formulation, solutions will be administered in a manner compatible with the dosage formulation and in such amount as is therapeutically effective. The formulations  
10 are easily administered in a variety of dosage forms, such as the type of injectable solutions described above, but drug release capsules and the like also can be employed.

For parenteral administration in an aqueous solution, for example, the solution should be suitably buffered if necessary and the liquid diluent first rendered isotonic with  
15 sufficient saline or glucose. These particular aqueous solutions are especially suitable for intravenous, intramuscular, subcutaneous and intraperitoneal administration. In this connection, sterile aqueous media which can be employed will be known to those of skill in the art in light of the present disclosure. For example, one dosage could be dissolved in 1 ml of isotonic NaCl solution and either added to 1000 ml of hypodermoclysis fluid or  
20 injected at the proposed site of infusion, (see for example, "Remington's Pharmaceutical Sciences" 15th Edition, pages 1035-1038 and 1570-1580). Some variation in dosage will necessarily occur depending on the condition of the subject being treated. The person responsible for administration will, in any event, determine the appropriate dose for the individual subject.

25

In addition to the compounds formulated for parenteral administration, such as intravenous or intramuscular injection, other pharmaceutically acceptable forms include, *e.g.*, tablets or other solids for oral administration; liposomal formulations; time release capsules; and any other form currently used, including cremes.

30

Oral formulations include such normally employed excipients as, for example, pharmaceutical grades of mannitol, lactose, starch, magnesium stearate, sodium saccharine, cellulose, magnesium carbonate and the like. These compositions take the form of solutions, suspensions, tablets, pills, capsules, sustained release formulations or powders. In certain defined embodiments, oral pharmaceutical compositions will comprise an inert diluent or assimilable edible carrier, or they may be enclosed in hard or soft shell gelatin capsule, or they may be compressed into tablets, or they may be incorporated directly with the food of the diet. For oral therapeutic administration, the active compounds may be incorporated with excipients and used in the form of ingestible tablets, buccal tablets, troches, capsules, elixirs, suspensions, syrups, wafers, and the like. Such compositions and preparations should contain at least 0.1% of active compound. The percentage of the compositions and preparations may, of course, be varied and may conveniently be between about 2 to about 75% of the weight of the unit, or preferably between 25-60%. The amount of active compounds in such therapeutically useful compositions is such that a suitable dosage will be obtained.

The tablets, troches, pills, capsules and the like may also contain the following: a binder, as gum tragacanth, acacia, cornstarch, or gelatin; excipients, such as dicalcium phosphate; a disintegrating agent, such as corn starch, potato starch, alginic acid and the like; a lubricant, such as magnesium stearate; and a sweetening agent, such as sucrose, lactose or saccharin may be added or a flavoring agent, such as peppermint, oil of wintergreen, or cherry flavoring. When the dosage unit form is a capsule, it may contain, in addition to materials of the above type, a liquid carrier. Various other materials may be present as coatings or to otherwise modify the physical form of the dosage unit. For instance, tablets, pills, or capsules may be coated with shellac, sugar or both. A syrup of elixir may contain the active compounds sucrose as a sweetening agent methyl and propylparabens as preservatives, a dye and flavoring, such as cherry or orange flavor.

### C. Examples

The following examples are included to demonstrate preferred embodiments of the invention. It should be appreciated by those of skill in the art that the techniques disclosed in the examples which follow represent techniques discovered by the inventor to function well in the practice of the invention, and thus can be considered to constitute preferred modes for its practice. However, those of skill in the art should, in light of the present disclosure, appreciate that many changes can be made in the specific embodiments which are disclosed and still obtain a like or similar result without departing from the spirit and scope of the invention.

10

#### EXAMPLE 1

##### Elucidation of a 3' Sequence of the GBV-B Genome

The inventors elucidated the previously unrecognized 3' terminal sequence of GBV-B (SEQ ID NO 1). This sequence was reproducibly recovered from tamarin serum containing GBV-B RNA, in RT-PCR nucleic acid amplification procedures using several different primer sets, and as a fusion with previously reported 5' GBV-B sequences.

There is information in the published literature reporting the putative sequences of the 5' and 3' termini of the GBV-B genome. The nucleic acid sequences of these termini were reportedly determined by ligating the ends of the viral RNA together, amplifying the sequence in the region of the resulting junction by reverse-transcription polymerase chain reaction (RT-PCR), and sequencing of the cDNA amplification product across the junction. However, the inventors believed these results required confirmation. Of particular concern was the fact that the 3' terminus appeared to be shorter than the equivalent region of other viruses in the family *Flaviviridae* (especially within the genus *Hepacivirus*) and that the reported 3' sequence lacked a defined RNA hairpin structure such as those present in these related viruses. Additional novel sequences at the 3' end of the GBV-B genome were investigated using a serum sample collected from a tamarin that was experimentally infected with virus. Amplification was used to determine the sequence of the 3' end.

First, serum (50  $\mu$ L) known to contain GBV-B RNA by RT-PCR assay was extracted with Trizol, and the RNA was washed and dried. A synthetic oligonucleotide was then ligated to the 3' end of the viral RNA. The oligonucleotide, AATTCGGCCCTGCAGGCCACAACAGTC, which was phosphorylated at the 5' end and chemically blocked at the 3' end, was ligated to the RNA essentially using the method described by Kolykhalov et al. (Behrens *et al.*, 1996). The RNA was initially dissolved in DMSO and the following additions were made: Tris-Cl, pH 7.5 (10 mM), MgCl<sub>2</sub> (10 mM), DTT (5 mM), hexamine cobalt chloride (1 mM), 10 pmol oligo and 8 U T4 ligase. The final concentration of DMSO was 30% in a final volume of 10  $\mu$ L. The ligation reaction was incubated for 4 or 20 hours at 19° C. 1  $\mu$ L of the ligation reaction was used directly to make cDNA, using a primer complementary to the ligated oligonucleotide and the Superscript 2 system, in a final volume of 15  $\mu$ L. 1  $\mu$ L of cDNA was amplified using the Advantage cDNA system (Clontech) and two additional oligonucleotide primers. These primers included one that was complementary to the ligated oligonucleotide (*i.e.*, “negative sense”) and a positive-sense primer located near the 3' end of the reported GBV-B sequence. A product approximately 290 bases in length was obtained, and this was gel purified and directly sequenced. Sequencing was done in both directions using the oligonucleotide primers employed for the amplification; 259 bases that had not been previously reported were identified as fused to the sequence that had been previously described as the 3' terminus of the viral genome.

To ensure that this novel 3' sequence from viral RNA could be reproducibly amplified, an additional 10  $\mu$ L of infected tamarin serum was extracted using Trizol. cDNA was prepared by reverse transcription using an oligonucleotide primer complementary to the penultimate 3' 25 bases of the novel sequence. Amplification was then done by PCR using the primer previously utilized for cDNA synthesis and a positive-sense primer mapping within the previously published GBV-B sequence. In the initial experiments, although a product was readily detected, DNA sequencing showed

that this product was missing all of the sequence distal to the poly-U tract. Carrying out the cDNA synthesis in the presence of DMSO circumvented this problem. A cDNA product of approximately 290 bases was obtained. This was sequenced and shown to consist of the 5' primer, 20 bases of the published GBV-B sequence, and 259 bases of the novel sequence obtained in the preceding experiments and containing the sequence of the 3' primer. The sequence of the 3' end of GBV-B is shown in SEQ ID NO: 1 (FIG. 1). The possible secondary RNA structure for this region is shown in FIG. 2, as predicted by a computer-based RNA folding program. The presence of a predicted hairpin structure at the extreme 3' end of this novel sequence is consistent with its location at the 3' terminus of the viral RNA.

The GBV-B cDNA (synthesis described above) was used as a template for PCR amplification of the 3' 1553 nucleotides (nts) of the GBV-B genome. This PCR amplification product was gel purified and cloned into plasmid DNA using the "Perfectly Blunt Cloning Kit" (Novagene).

## EXAMPLE 2

### Construction of an Infectious GBV-B Clone

The elucidation of a 3' sequence of the GBV-B genome will allow those of skill in the art to construct and validate an infectious molecular clone of GBV-B. This will be done using the following procedures.

A full-length cDNA copy of the GBV-B genome containing the newly identified 3' terminal sequences was constructed. RNA transcribed from this cDNA copy of the genome will be infectious when inoculated into the liver of a GBV-B permissive tamarin, giving rise to rescued GBV-B virus particles.

A 1:1000 dilution of GBV-B infectious tamarin serum was obtained. This material was used as a source of viral RNA for the amplification of GBV-B nucleic acid sequences by reverse-transcription polymerase chain reaction. For amplification of

previously reported segments of the GBV-B genome, 250  $\mu$ L of the diluted serum was extracted with Trizol using the manufacturer's instructions. The final RNA pellet was dissolved in 10  $\mu$ L of a 100 mM DTT buffer containing 5% RNasin. This material was converted into cDNA using Superscript 2 reverse transcriptase and oligonucleotide primers designed to be complementary to the reported GBV-B RNA sequence and to contain unique restriction sites. This cDNA was amplified using the Advantage cDNA kit (Clontech) employing the cDNA primer (negative sense) as the downstream primer and a similar positive-sense upstream primer, again containing a unique restriction site.

The published sequence of GBV-B allowed for the selection of primers in convenient areas of the genome containing unique restriction sites. Using this general strategy, the inventors amplified segments of the reported GBV-B genome representing: (1) nucleotides (nts) 1-1988, using an upstream primer containing a T7 RNA polymerase promoter and a BamH1 site upstream of nt 1, and a downstream primer containing a unique EcoR1 site (nt 1978); (2) nts 1968-5337, using a downstream primer containing a unique Cla1 site at position 5027; (3) nts 5317- 7837, using a downstream primer containing a Sal1 site at nt 7847; and, (4) nts 7837-9143, using a downstream primer containing an added Xho1 site. It was found necessary to use different PCR conditions for each primer set.

The RT-PCR products generated in these reactions were cloned into plasmid DNA after gel purification, using the "Perfectly Blunt Cloning Kit" (Novagene). Ten bacterial colonies from each of the four RT-PCR products were analyzed for insert size by restriction endonuclease digestion using EcoR1, the sites for this enzyme being located on either side of the insert in the resulting plasmids. For three of the RT-PCR amplicons, 9 of 10 colonies contained plasmids with the correct size insert. The EcoR1-Cla1 amplicon generated only 1/10 colonies with a correct size insert. Thus, 30 additional colonies were examined, yielding two more clones with insert of the correct size. For each of these plasmids, simple restriction patterns were obtained using two restriction enzymes. As these appeared to be correct, the plasmid DNAs were subjected to sequencing using an ABI automatic sequencer.

### EXAMPLE 3

#### Nucleotide sequence of the cloned GBV-B cDNA

The 5' region of the cloned sequence revealed a relatively long nontranslated region corresponding to the published sequence of the GBV-B 5'NTR, which includes an IRES. This region was followed by a long open reading frame. Near the 3' end of the genome a poly-U tract was identified; however, this was shorter than the published 3' homopolymeric poly-U region. The sequence from these clones was compared with those in the GenBank database (Accession U22304, "Hepatitis GB virus B polypeptide complete genome"). Twenty-two nucleotide differences were identified, of which 14 gave rise to amino acid changes (Table 1). In order to determine whether these changes were genuine or RT-PCR artifacts, which could have been introduced due to the very small amount of material from which these sequences were amplified, segments of the genome containing these changes were reamplified using a serum sample from an independently infected tamarin. Of the 14 changes noted in the original cDNA clones, 12 were not present in these newly amplified sequences and thus were probably RT-PCR artifacts (Table 2.). A particularly interesting difference from the published GenBank sequence, however, which was present in both the original clones as well as a repeat amplification, was a two-nucleotide substitution that obliterated the SalI site present in the published sequence.

**Table 1. Differences in the amino acid sequences of GBV-B cDNA clones and the GBV-B sequence reported by Simons *et al.* (1995).**

GBV-B Protein	AMINO ACID Δ FROM ABBOTT SEQUENCE	RT-PCR Products from Tamarin 12024 (PCR Reaction #)
Core	G <sub>99</sub> →S	G (38.1a)
E1	V <sub>395</sub> →I	V (40.2a)
E2	D <sub>703</sub> →N	D (42.3a)
E2	P <sub>706</sub> →Q	H (42.3a)

E2	A <sub>728</sub> →V	A (42.3a)
NS2	L <sub>791</sub> →F	F(42.3a)
NS2	T <sub>804</sub> →A	A(42.3a)
NS5A	L <sub>1990</sub> →M	L (46.5a)
NS5A	I <sub>2082</sub> →T	I (46.5a)
NS5A	S <sub>2174</sub> →P	(not done)
NS5A	G <sub>2228</sub> →E	E (48.6a)
NS5A	T <sub>2233</sub> →S	T (48.6a)
NS5A	A <sub>2236</sub> →V	A (48.6a)
NS5B	V <sub>2833</sub> →I	V (50.7a)

#### EXAMPLE 4

##### Construction of a full-length GBV-B cDNA clone.

5 The four GBV-B cDNA inserts described above were cloned into Bluescript ks+ using unique restriction sites. Since the unique SalI site that was reported to be present in the published GBV-B sequence (nt position 7847) was absent in these cDNA clones, this restriction site was created by engineering two silent nucleotide changes using the "Quick Change" mutagenesis system (Stratagene). Although the most 5' clones (nucleotides 1-

10 7847) could be readily constructed, attempts to add the remaining 3' clones were unsuccessful due to rearrangements and deletions. This problem was overcome by use of pACNR1180, a plasmid that had been used to construct an infectious clone of yellow fever virus. Finally, the most 3' 771 nucleotides of GBV-B were excised from the plasmid containing the novel, previously unreported 3' sequence, and inserted into the

15 truncated assembled GBV-B cDNA construct to complete the 3' end. The 3' terminus of this full-length cDNA was then subjected to DNA sequencing to confirm its integrity. Extensive restriction digests indicated that this construct had the characteristics of a full-length cDNA copy of GBV-B virus. Because there is not yet an understanding of which cultured cells (if any) might be permissive for GBV-B replication, the infectivity of the

20 synthetic GBV-B RNA will be assessed by injecting the RNA directly into the liver of a susceptible tamarin.

Alternatively, an infectious full-length clone can be produced by the following protocol. A plasmid will be made containing a cassette including the 5' and 3' ends of the virus flanked by appropriate restriction sites. These constructs have been shown to efficiently translate reporter genes, with transcription taking place via a T7 promoter placed immediately upstream of the 5'NTR (*e.g.*, see Rijnbrand *et al.*, 1999). The major portion of the GBV-B genome would then be amplified by long range RT-PCR. This method is now well established for hepatitis C virus and other flaviviruses (Teller *et al.*, 1996), and it has been used successfully also to amplify rhinovirus RNA. Briefly this technique uses "Superscript" reverse transcriptase to synthesize cDNA and a mixture of "KlenTaq 1", and "DeepVent" polymerases to amplify this cDNA. Primers that can be used will contain restriction sites to allow cloning of the RT-PCR products into the cassette vector. After being transformed into suitable competent bacteria, extensive restriction analysis will enable us to determine which clones contain inserts that are of full length and which have a high probability of being correct. Apparent full-length clones will be analyzed further by coupled transcription-translation using the Promega "TnT" system, with the addition of microsomal membranes to allow the cleavage of the structural proteins by cellular signalase enzymes. Clones which appear correct by restriction analysis and which produce GBV-B proteins, in particular the protein coded for by the extreme 3' end of the genome, NS5B, will be selected, and RNA will be transcribed from these clones using the Ambion MegaScript system. "Correct" looking clones (>10) can be injected directly into a tamarin liver at several sites. A successful infection will be determined as described below. If a positive signal is detected the entire genome will be amplified and sequenced to determine which plasmid the virus originated from.

## EXAMPLE 5

### Rescue of Infectious GVB-B

Infectious GBV-B will be rescued from synthetic genome-length RNA following its injection into the liver of tamarins (*Saquinus sp.*). In past studies, HAV from synthetic RNA in owl monkeys has been recovered (*Aotus trivirgatus*) (Shaffer *et al.*, 1995), and

more recently, the recovery of virus from a chimpanzee injected intrahepatically with RNA transcribed from a full-length genotype 1b HCV cDNA clone was reported (Beard *et al.*, 1999).

5 RNA will be prepared for these experiments using the T7 MegaScript kit (Ambion) and a total of 10 µg of plasmid DNA as template. An aliquot of the reaction products will be utilized to ensure the integrity of the RNA by electrophoresis in agarose-formaldehyde gels. The remainder of the transcription reaction mix will be frozen at  
10 -80C° until its injection, without further purification, into the liver of a tamarin. Because of the small size of the tamarin, the RNA will be injected under direct visualization following a limited incision and exposure of the liver. Under similar conditions, in other primate species, RT-PCR-detectable viral RNA or cDNA has not been detected in serum samples collected within days of this procedure in the absence of viral replication (Kolykhalov *et al.*, 1997; Yanagi *et al.*, 1998; Beard *et al.*, 1999). Thus, the appearance  
15 of RNA in serum collected subsequently from these tamarins will be strong evidence for the replication competence of the synthetic RNA. Serum will be collected weekly for six weeks, then every other week for an additional 6 weeks from inoculated animals. In addition to RT-PCR for detection of viral RNA (see Fig. 2B), alanine aminotransferase (ALT) levels will be measured as an indicator of liver injury and to assess liver histology  
20 in punch biopsies taken at the time of ALT elevation. Maximum viremia and an acute phase ALT response is expected to occur around 14-28 days post-inoculation of infectious RNA (Simons *et al.*, 1995; Schlauder *et al.*, 1995; Karayiannis *et al.*, 1989). Transfections will be considered to have failed to give rise to infectious virus if RNA is not detected in the serum within 12 weeks of inoculation. Successfully infected animals  
25 will be followed with twice weekly bleeds until resolution of the viremia, or for 6 months, whichever is longest.

## EXAMPLE 6

### Construction of GBV-B/HCV Chimeras

The GBV-B genome can be used as the acceptor molecule in the construction of chimeric viral RNAs containing sequences of both HCV and GBV-B. Such constructs will allow one to investigate the mechanisms for the different biological properties of these viruses and to discover and investigate potential inhibitors of specific HCV activities (*e.g.*, proteinase) required for HCV replication. Different classes of chimeric viruses are contemplated. These include: (a) replacement of the GBV-B IRES with that of HCV; and (b) replacement of the NS3 major serine proteinase and helicase, and (c) the replacement of the NS5B RNA-dependent RNA polymerase with the homologous proteins of HCV.

The chimeric constructs described in the following sections will be made by PCR mutagenesis, using high fidelity polymerases and oligonucleotide primers designed to include the specific fusions of GBV-B and HCV sequences (Landt *et al.*, 1990). First round PCR reactions will create the desired fusion, and generate a new “primer” to be used in a second PCR reaction spanning the region to a convenient unique restriction site. PCR cycles will be kept to the minimum number necessary for successful amplification, and all segments of viral sequence that are amplified by PCR will be subjected to DNA sequencing to exclude the presence of unwanted PCR-introduced errors. Sequencing will be accomplished at UTMB’s core Recombinant DNA Laboratory. Amplified segments will be kept to the minimum by the exchange of cloned cDNA segments spanning convenient restriction sites in subgenomic clones, and where necessary PCR artifacts can be corrected by site-directed mutagenesis (QuickChange mutagenesis kit, Stratagene).

A number of viable positive-strand RNA virus chimeras have been constructed previously in which IRES elements have been swapped between different viruses. Most of these chimeras have involved the exchange of IRES elements between picornaviruses. Others have been successful in constructing viable poliovirus chimeras containing the HCV IRES in place of the native poliovirus IRES (Zhao *et al.*, 1999; Lu and Wimmer, 1996). A similar rhinovirus 14 chimera containing the HCV IRES has been constructed, although its replication phenotype is not as robust as the poliovirus chimera described by

Lu and Wimmer (Lu and Wimmer, 1996). More importantly, Frolov et al. (Frolov *et al.*, 1998) recently reported chimeric flaviviruses in which the HCV IRES was inserted into the genetic background of a pestivirus, bovine viral diarrhea virus (BVDV) in lieu of the homologous BVDV sequence. Although these viable chimeric polioviruses and pestiviruses replicate in cell cultures, they are poor surrogates for HCV in animal models as neither virus is hepatotropic or causes liver disease. Importantly, Frolov *et al.* (Frolov *et al.*, 1998) demonstrated quite convincingly that the requirement for cis-acting replication signals at the 5' terminus of the pestivirus genome was limited to a short tetranucleotide sequence. This requirement presumably reflects the need for the complement of this sequence at the 3' end of the negative strand during initiation of positive-strand RNA synthesis. The work of Frolov *et al.* shows that the IRES of BVDV does not contain necessary replication signals, or that if these are present within the BVDV IRES they can be complemented with similar signals in either the HCV or encephalomyocarditis virus (EMCV, a picornavirus) IRES sequence. Since GBV-B and HCV are more closely related to each other than BVDV and HCV, these studies provide strong support for the viability of chimeras containing the HCV IRES in the background of GBV-B.

Construction of a viable IRES chimera will be enhanced by studies that have documented the sequence requirements and secondary structures of the IRES elements of both HCV and GBV-B (*see* Lemon and Honda, 1997; Honda *et al.*, 1996; Rijnbrand *et al.*, 1999). To a considerable extent, the work of Frolov et al. (Frolov *et al.*, 1998) was guided by studies of the HCV IRES structure. More recently, these studies have been extended to include a detailed mutational analysis of the GBV-B IRES. The results of these experiments indicate that the functional IRES of GBV-B extends from the 5' end of structural domain II (nt 62) to the initiator AUG codon (nt 446). This segment of the full-length GBV-B clone will be replaced with HCV sequence extending from 5' end of the analogous domain II within the HCV IRES (nt 42) to the initiator codon at the 5' end of the HCV open reading frame (nt 341) to construct the candidate chimera, "GB/C:IRES". The source of HCV cDNA for these studies will be the infectious HCV clone, pCV-

H77C, which contains the sequence of the genotype 1a Hutchinson strain virus (Yanagi *et al.*, 1998), whose infectivity in a chimpanzee following intrahepatic inoculation with synthetic RNA transcribed from pCV-H77C has been confirmed.

- 5            This GB/C:IRES construct will retain two upstream hairpins within the GBV-B sequence (stem-loops Ia and Ib), and it is thus analogous to the viable “BVDV+HCVdelB2B3H1” chimera of Frolov *et al.* (Frolov *et al.*, 1998). A second chimera can be constructed in which the entire HCV 5’ nontranslated RNA will be inserted in lieu of nts 62-446 of the GBV-B genome (“GB/C:5’NTR”). This construct
- 10 will add to the inserted HCV sequence the most 5’ stem-loop from HCV (stem-loop I). A similar insertion was shown to substantially increase the replication capacity of BVDV+HCVdelB2B3H1 by Frolov *et al.* (Frolov *et al.*, 1998), providing a replication phenotype similar to wild-type BVDV in cell culture.
- 15            It is important to point out that there is strong evidence from multiple lines of investigation indicating that it will not be necessary to include coding sequence in these IRES chimeras. This is the case even though Reynolds *et al.* (Reynolds *et al.*, 1995) have argued that the HCV IRES extends past the initiator codon, and into the core-coding region of that virus. Although Lu and Wimmer (Lu and Wimmer, 1996) found it
- 20 necessary to include HCV core sequence to obtain a viable chimeric poliovirus, the BVDV chimeras reported by Frolov *et al.* (Frolov *et al.*, 1998) did not contain any HCV coding sequence. This discrepancy may be explained by the observation that the only downstream requirement for full activity of both the GBV-B and HCV IRES elements is the presence of an unstructured RNA segment (Honda *et al.*, 1996; Rijnbrand *et al.*,
- 25 Presumably, this facilitates interaction of the viral RNA with the 40S ribosome subunit in the early steps of cap-independent translation (Honda *et al.*, 1996). The 5’ GBV-B coding sequence fulfills this criterion (Rijnbrand *et al.*, 1999).

## EXAMPLE 7

### ***In vitro* Characterization of the Translational Activity of IRES Chimeras**

The fidelity of the genome-length chimeric constructs will be confirmed by sequencing any DNA segments that have been subjected to PCR during the construction process, as well as confirming sequence at the junction sites. In addition, the translational activity of synthetic RNA derived from these constructs will be assessed and compared to the translational activity of the wild-type GBV-B and HCV RNAs. These studies will be carried out in a cell-free translation assay utilizing rabbit reticulocyte lysates (Rijnbrand *et al.*, 1999). Synthetic RNA will be produced by runoff T7 RNA polymerase transcription using as template ClaI-digested plasmid DNA (BamHI digestion in the case of the genome HCV construct) (T7 Megascript kit, Ambion). <sup>3</sup>H-UTP will be added to the reaction mix to allow for quantification of the RNA product. Reticulocyte lysates (Promega) will be programmed for translation by the addition of RNA (at least 50% full-length as determined by agarose gel electrophoresis) at 20, 40 and 80 µg/ml, and translation reactions will be supplemented with microsomal membranes (Promega). <sup>35</sup>S-Methionine-labelled translation products will be separated by SDS-PAGE, and the quantity of E1 protein produced from each RNA determined by PhosphorImager analysis (Molecular Dynamics). Comparisons of the activity of the HCV IRES in the background of GBV-B and HCV will take into account differences in the methionine content of the E1 proteins of these viruses. Based on previous studies of both the GBV-B and HCV IRES elements (Honda *et al.*, 1996; Rijnbrand *et al.*, 1999), it is expected that these studies will confirm that the HCV IRES will retain nearly full activity when placed within the GBV-B background.

## EXAMPLE 8

### ***In vivo* Characterization of IRES Chimeras**

Synthetic RNAs produced from each of the two chimeric GBV-B/HCV constructs (GB/C:IRES and GB/C:5'NTR) will be tested for their ability to induce infection and cause liver disease in susceptible tamarins. These experiments will be carried out as

described in Example 2. GB/C:5'NTR may generate viremia and liver injury more closely resembling that observed with wild-type GBV-B infection (Frolov *et al.*, 1998).

## EXAMPLE 9

### 5            **Chimeric Flaviviruses Containing the HCV NS3 Serine Proteinase/Helicase                  within the GBV-B Background**

Chimeric flaviviruses containing the HCV NS3 serine proteinase/helicase within the GBV-B background are also contemplated within the present invention. The construction of chimeric flaviviruses containing specific heterologous functional

---

10 polyprotein domains, however, poses a number of special problems. Unlike the situation with the IRES, where the relevant RNA segments appear to have a unique function restricted to cap-independent translation initiation and interact with host cell macromolecules, viral proteins often have multiple functions and may form specific macromolecular complexes with other viral proteins that are essential for virus replication

15 (Lindenbach and Rice, 1999). Furthermore, such chimeric polyproteins must be amenable to efficient processing by the viral proteinases (NS2/NS3 or NS3). This requires knowledge of the proteinase cleavage specificities as well as specific sites of proteolytic cleavage. Although to date there have been no published studies of the processing of the GBV-B polyprotein, the relatively close relationship between GBV-B

20 and HCV, about 30% overall amino acid identity within the polyprotein (Muerhoff *et al.*, 1995), allows good computer predictions of the alignments of these proteins. The crystallographic structures of both the proteinase and helicase domains of the HCV NS3 protein have been solved (Yao *et al.*, 1997). Thus, both linear alignments and models of the 3D structure of the NS3 proteins of these viruses can provide guidelines for designing

25 specific chimeric fusions that are likely to preserve function.

## EXAMPLE 10

### **NS3 Proteinase-Domain Chimeras**

In HCV, NS3 contains the major serine proteinase that is responsible for most

30 cleavage events in the processing of the nonstructural proteins, *i.e.*, those that occur at the

NS3/4A, 4A/4B, 4B/5A and 5A/5B junctions. The active proteinase domain of HCV is located within the amino terminal third of the NS3 protein (residues 1-181), which shares 31% amino acid identity with the analogous segment of the GBV-B polyprotein (GBV-B vs HCV-BK) (Muerhoff *et al.*, 1995). Importantly, the active site of this proteinase appears to be particularly well conserved in GBV-B. The GBV-B proteinase maintains the residues that are responsible for catalysis and zinc binding in the HCV enzyme (Muerhoff *et al.*, 1995), and unlike the NS3 proteinases of some other flaviviruses preserves the Phe-154 residue that determines in part the  $S_1$  specificity pocket of the enzyme and the preference of the HCV proteinase for substrates with a cysteine residue at the P1 position (Scarselli *et al.*, 1997). Thus, it is not surprising that the relevant proteolytic cleavage sites within the GBV-B polyprotein that are predicted from alignments with the HCV polyprotein all possess a Cys residue at this position. Of greatest significance for the proposed experiments, however, is the work of Scarselli et al. (Scarselli *et al.*, 1997) who demonstrated that the GBV-B NS3 proteinase is able to effectively process the polyprotein of HCV in experiments carried out *in vitro*. Using synthetic peptide substrates, these investigators demonstrated that the enzymatic activities of the GBV-B proteinase (residues 1-181) had kinetic parameters similar to the HCV proteinase on NS4A/4B and NS4B/4A substrates HCV. They did not possess reagents allowing a determination of whether the HCV proteinase is able to cleave a GBV-B substrate, but their results indicate that these viral proteinases share important functional properties. Therefore, these similarities suggest that the HCV proteinase could function in lieu of the GBV-B proteinase if used to replace this segment of an infectious GBV-B clone. In addition, experiments with sindbis/HCV chimeras have shown that the HCV proteinase can cleave within the framework of a sindbis polyprotein (Filocamo *et al.*, 1997).

In considering the design of these NS3 proteinase chimeras, there are two additional important considerations. First, in HCV, the cleavage between NS2 and NS3 occurs *in cis*, as the result of a zinc-dependent metalloproteinase that spans the NS2/NS3 junction (Hijikata *et al.*, 1993). As only the NS3 sequences will initially be exchanged,

the viability of the resulting chimeras will be dependent upon preservation of the *cis*-active cleavage across a chimeric NS2/NS3 proteinase domain. The alignment of GBV-B and HCV sequences shows that residues in HCV that have been shown by Grakoui *et al.*, 1993, to be essential for the NS2/NS3 cleavage are conserved in GBV-B (Muerhoff *et al.*, 1995). Additional chimeras that will include the relevant carboxyl-terminal portion of NS2 can also be created.

A second important consideration is that the mature HCV NS3 proteinase functions as a noncovalent assembly of the NS3 proteinase domain and the amino terminal portion of NS4A, a proteinase accessory factor. The details of this association are well known, and have been studied at the crystallographic level (Kim *et al.*, 1996). The N-terminal domain of the folded proteinase contains eight  $\beta$  strands, including one contributed directly by the NS4A peptide backbone. X-ray studies have shown that this array of  $\beta$  strands gives rise to a much more ordered N-terminus. Thus, the presence of the NS4A strand seems likely to contribute to the structure of the substrate-binding pocket. It is not known whether the NS3 proteinase of GBV-B also requires a similar interaction with NS4A of that virus for complete activity, or, if so, whether the NS4A of GBV-B could substitute for NS4A of HCV in forming the fully active NS3 proteinase of HCV. The predicted GBV-B NS4A molecule is 54 amino acid residues in length (Simons, *et al.*, 1995; Muerhoff *et al.*, 1995), just as in HCV. However, the level of amino acid homology between the NS4A molecules is not especially high, and the potential interaction with either NS3 molecule cannot be predicted from this sequence on the basis of available knowledge. To overcome this potential problem, chimeras will be created in which not only the NS3 proteinase domain of GBV-B is replaced, but also the relevant NS4A segment as well, with homologous segments of the HCV polyprotein. The interaction of the HCV NS3 and NS4A domains represents a unique target for antiviral drug design, and it would be beneficial to have this specific interaction present in any virus to be used as a surrogate for HCV in the evaluation of candidate antiviral inhibitors of HCV proteinase *in vivo*.

The NS3 proteinase chimeras that can be made include “GB/C:NS3<sup>p</sup>”, which will contain the sequence encoding the first 181 amino acid residues of the HCV NS3 molecule in lieu of that encoding the first 181 residues of GBV-B NS3, and “GB/C:NS3<sup>p</sup>4A”, which will include the same NS3 substitution as well as the HCV sequence encoding the amino-terminal segment of NS4A that forms the interaction with NS3. The precise NS4A sequence to be included in the latter chimera will be based on the modeling studies, which may also suggest more effective fusions of the NS3 proteinase domain of HCV with the downstream NS3 helicase domain of GBV-B. The source of HCV cDNA for these experiments will be the infectious HCV clone, pCV-H77C, which contains the sequence of the genotype 1a Hutchinson strain virus (Yanagi *et al.*, 1998).

## EXAMPLE 11

### NS3 Helicase Domain Chimeras

In addition to serine proteinase activity located within the amino-third of NS3, the downstream carboxy-terminal two-thirds of the molecule contains an RNA helicase activity. These two functional domains appear to be separated by a flexible spacer, within which the fusion of HCV proteinase or helicase domain sequences with GBV-B sequence will be placed. The exact role of the helicase in the HCV life-cycle is not known, but it is almost certainly required for dsRNA strand-separation during some phase of viral RNA synthesis. The helicase domains of GBV-B and HCV are remarkably well conserved, with some regions within the helicase showing as much as 55% amino acid identity (Muerhoff *et al.*, 1995). The GBV-B helicase is more closely related to the HCV helicase than all other flaviviral NS3 helicases, and it preserves many residues found within the conserved helicase motifs of HCV. Thus the HCV NS3 helicase may be capable of functioning when placed within the polyprotein of GBV-B, and such a chimeric virus may be capable of replication. Residues 182-620 of the GBV-B NS3 molecule will be substituted with the analogous segment of HCV (Fig. 5, “GB/C:NS3<sup>h</sup>”). A chimera will also be made in which the entire NS3 and amino terminal NS4 protein sequences of GBV-B is replaced with the homologous HCV sequences (“GB/C:NS3-

4A”). The latter construct will thus represent a dual proteinase-helicase chimera. As with the proteinase chimeras, the HCV cDNA will be derived from pCV-H77C (Yanagi *et al.*, 1998).

5

## EXAMPLE 12

### *In vitro* Characterization of NS3 and NS3-NS4A Chimera

Prior to being evaluated for infectivity in susceptible tamarins, RNAs produced *in vitro* from these clones will be characterized *in vitro*. This evaluation will be restricted to a documentation of the proper processing of the expressed polyprotein (*i.e.*, NS2/NS3 and NS3 proteinase functions), since there are no relevant assays that can determine whether the helicase or RNA-dependent RNA polymerase activities in these polyproteins are sufficient for virus replication. The proteolytic processing of the polyprotein is important, however, as it may be altered either by inclusion of the heterologous HCV NS3 proteinase in lieu of the natural GBV-B protease, or by a change in the folding of the polyprotein induced by inclusion of HCV sequence anywhere within the polyprotein. These studies will be carried out in cell-free coupled transcription/translation assays (“TnT” system, Promega) supplemented with microsomal membranes. Template DNAs will be digested with SalI, which restricts the cDNA within the NS5B coding region. <sup>35</sup>S-methionine-labelled translation products will be separated by SDS-PAGE, and the mature NS3 protein identified by its apparent molecular mass. The NS3 and NS5B proteins will be identified by immunoblot analysis using rabbit antisera to the GBV-B NS3 and NS5B proteins. Generation of a mature ~68 kDa NS3 protein will provide proof of both the *cis*-active NS2/NS3 cleavage and the NS3-mediated cleavage of NS3/NS4A. Similarly, identification of a mature, processed NS5B molecule will provide further support for the activity of the NS3 proteinase. Controls for these experiments will be the wild-type GBV-B polyprotein expressed in similar fashion from the full-length GBV-B clone. If necessary to more clearly demonstrate the processing of the nonstructural proteins in these constructs, subclones representing the nonstructural region of the chimeric sequences could be produced.

30

### EXAMPLE 13

#### *In vivo* Characterization of NS3 and NS3-4A Chimeras

Synthetic RNAs produced from each of the chimeric GBV-B/HCV constructs described in the preceding section will be tested for their ability to induce infection and  
5 cause liver disease in susceptible tamarins. These experiments will be carried out using the approach described above.

### EXAMPLE 14

#### Chimeric Flaviviruses Containing the HCV NS5B RNA Dependent

#### 10 RNA Replicase within the GBV-B Background

The HCV NS5B molecule contains an RNA-dependent RNA polymerase that plays a central role in replication of the virus. Although this molecule represents a prime target for drug discovery efforts, it has proven difficult to express NS5B in a form that retains enzymatic activity specific for HCV RNA as a substrate. Thus, relatively little is  
15 known of the functional activity of the HCV replicase, including structure-function relationships of NS5B. Despite this, the NS5B proteins of GBV-B and HCV appear to be functionally closely related, as they share as much as 43% amino acid identity (Muerhoff *et al.*, 1995). A more important question may be whether an RNA dependent RNA polymerase can act on foreign substrates. However, published work has shown that *in*  
20 *vitro* purified HCV polymerase has very little specificity for its template, using hepatitis C or globin message with equal fidelity (Behrens *et al.*, 1996; Al *et al.*, 1998). This finding is very similar to that obtained with picornaviral polymerases, where it has been known for many years that *in vitro* the enzyme exhibits very little specificity. It has  
25 always been considered highly likely that this situation would not pertain *in vivo* where it was thought that the interaction of viral or cellular factors with the 3' end of the genome would generate template specificity. However, recent reports have shown that the removal of the entire 3' untranslated sequence (leaving, however, the poly(A) region present) from both the poliovirus and rhinovirus genome does not completely abrogate the infectivity of the virus (Todd *et al.*, 1997). Furthermore, virus, which was recovered  
30 after the initial transfections, was shown to have recovered much of the infectivity of the

original virus (Todd *et al.*, 1997). The mechanism for this recovery of infectivity is at present unknown, but these results suggest that the HCV polymerase may be able to function to replicate infectious GBV-B/HCV NS5B chimeras.

5           Thus a chimeric genome-length virus can be created in which the NS5B coding sequence of HCV (amino acids 2422-3014, 593 residues) is inserted within the background of GBV-B in lieu of its native RNA-dependent RNA polymerase (amino acids 2274-2864, 591 residues). This chimeric virus would be valuable for animal studies of candidate antiviral inhibitors of HCV RNA synthesis.

10

          This NS5B chimera would be evaluated to determine that there was proper proteolytic processing of the polyprotein. This would be accomplished by expression of the chimeric polyprotein in a coupled translation-transcription reaction, followed by immunoblot analysis for the mature NS5B protein, as described for the NS3 and NS3-4A  
15       chimeras in the preceding section. If these results confirm that the GB/C:5B chimeric polyprotein is processed with release of NS5B, experiments in tamarins would progress to determine whether synthetic RNA transcribed from the clone is infectious and capable of causing liver disease in intrahepatically inoculated animals. These experiments would be carried out as described above.

20

          A chimeric molecule can be constructed from an infectious GBV-B clone in which the HCV NS3 proteinase or proteinase/helicase sequence would be placed in frame in lieu of the homologous GBV-B sequence, and this chimeric cDNA would be used to generate infectious GBV-B/HCV chimeric viruses by intrahepatic inoculation of  
25       synthetic RNA in tamarins. Published studies indicate that the GBV-B and HCV proteinases have closely related substrate recognition and cleavage properties, likely making such chimeras viable and capable of initiating viral replication in appropriate cell types.

## EXAMPLE 15

### Chimeric Viruses Containing HCV Structural Proteins within a GBV-B Genetic Background, and GBV-B Structural Proteins within an HCV Background

It is well documented that the structural proteins of one flavivirus may in some cases be substituted for those from another member of the family. Such chimeric viruses have been recovered from viruses as distantly related to each other as dengue virus and tick-borne encephalitis virus (Pletnev *et al.*, 1992). More recently, the prM and E proteins of Japanese encephalitis virus have been used to replace the equivalent proteins in a vaccine strain of yellow fever virus to produce a JE/YF chimera (Chambers *et al.*, 1999).

These observations suggest that chimeras in which the structural proteins of HCV have been used to replace the homologous proteins of GBV-B may well be viable and capable of replication. The isolation of a chimeric virus containing HCV structural proteins, but having the growth characteristics of GBV-B virus, could answer many fundamental questions concerning the structure and interaction of these proteins in HCV. They would also be useful in addressing the nature of the immune response to HCV structural proteins in infected primates (Farci *et al.*, 1992). More to the point of this application, the availability of such chimeric viruses would allow studies of candidate HCV vaccines to be carried out in the tamarin model. This would be a major advance, because at present such studies are limited to chimpanzees (Choo *et al.*, 1994).

The basis for the difference in the host ranges of HCV and GBV-B is completely unknown. Among many other possibilities, it is conceivable that the host range is dependent upon the availability of a specific receptor(s). If this were the case, host range might be dependent upon the envelope proteins that must interact with the putative cellular receptor. Thus, a chimeric virus containing the envelope proteins of HCV within the genetic background of GBV-B might be noninfectious in tamarins (but potentially infectious in chimpanzees). Thus, a finding that both structural protein chimeras are noninfectious in the tamarin, may require the construction of complementary chimeras in which the relevant GBV-B structural proteins will be inserted into the background of an infectious HCV clone. If inclusion of the GBV-B envelope proteins within the backbone

of HCV confers on the resulting chimera the ability to replicate in tamarins, it will confirm an important role for the structural proteins in defining the different host ranges of these viruses. More importantly, the resulting virus would be an exceptionally valuable resource for future studies as it would contain all of the nonstructural replication elements, as well as the 5' and 3' nontranslated regions, of HCV. Such a virus would allow the tamarin model to be used to address many unresolved issues in HCV biology and pathogenesis.

## EXAMPLE 16

### 10                    **Construction and Evaluation of Structural Protein Chimeras**

15                    In designing structural protein chimeras, it is important to note that the two envelope proteins of HCV, E1 and E2, form noncovalent heterodimeric complexes that are likely to be important in the assembly of infectious virus particles. This is not known to be the case with the envelope proteins of GBV-B, but it is likely given similarities in the sizes and hydropathy profiles of these proteins (Simons *et al.*, 1995; Muerhoff *et al.*, 1995). Accordingly, the E1 and E2 proteins will be replaced as a unit, and chimeras containing only one of these proteins from the heterologous virus will generally not be produced. First, a chimera will be created where the E1 and E2 regions of GBV-B virus are replaced with those of HCV, "GB/C:E1-2". The source of HCV cDNA for these constructions will be pCV-H77C (Yanagi *et al.*, 1998). A chimera will also be made in which the core protein, in addition to the envelope proteins, is replaced with the homologous proteins of HCV ("GB/C:Co-E2"). Additional chimeras will be made to determine whether tamarins can be infected with chimeras containing the GBV-B structural proteins within the genetic background of HCV. These will include "C/GB:E1-2" and "C/GB:Co-E2". The backbone for these chimeras will be pCV-H77C, the infectious genotype 1a cDNA clone developed in the Purcell laboratory at NIAID (Yanagi *et al.*, 1998).

30                    The specific amino acid sequences of GBV-B to be replaced with the homologous segments of HCV have been determined by alignments of the GBV-B and HCV

sequences, coupled with the location of signalase cleavage sites predicted to be present within the amino terminal third of the GBV-B polyprotein using the computer algorithm of Von Heijne. These predicted signalase cleavages lie between residues 156/157 (core/E1), aa 348-349 (E1/E2) and 732/733 (E2/NS2) in the GBV-B sequence. Thus, the chimera GB/C:E1-2 will contain sequence encoding HCV aa 192-809 in lieu of that encoding aa 157-732 in GBV-B, while the insertion in the GB/C:Co-E2 chimera will extend from the initiator AUG codon (aa 1) to residue 809 in HCV, and will be spliced into GBV-B in lieu of the segment encoding aa 1-732 in the GBV-B clone. The complementary chimeras to be constructed within the background of HCV will involve exchanges of the same segments of the genomes.

### EXAMPLE 17

#### Characterization of Structural Protein Chimeras

Prior to being evaluated for infectivity in tamarins, the processing of these chimeric polyproteins will be examined in coupled transcription/translation reactions supplemented with microsomal membranes, as described in the preceding sections for the proteinase and other proposed chimeras. If these results confirm that the polyprotein is processed as expected, with production of glycosylated E1 and E2 proteins from each of the chimeras (and seen in similar experiments with HCV proteins), studies would proceed in tamarins as previously described. The results of these studies may provide novel information on the basis of the host range differences that exist between HCV and GBV-B. If these results suggest that the envelope proteins play a critical role in determining host range, additional experiments could be carried out with these chimeras in chimpanzees (which are permissive for HCV but apparently not for GBV-B).

### EXAMPLE 18

#### Further Characterization of Rescued Chimeric Viruses

Where infection with chimeric viruses is induced in animals that are injected within the liver with synthetic RNA, this virus will be passaged in GBV-B naïve tamarins to further characterize the nature of the infection induced by the chimera. This will be

accomplished by taking a pool of the 3 highest titer GBV-B RNA-containing serum specimens from the animal that was successfully transfected with RNA, and inoculating 1 mL of a 1:100 dilution of this pool intravenously into two susceptible animals. These animals will be monitored for infection and liver disease. These animals will be followed  
5 until resolution of the viremia and appearance of antibodies detectable in immunoblots with GST-NS3 protein expressed in *E. coli*, or for at least 6 months should an animal sustain a chronic infection. RT-PCR amplification of chimeric segments of the genome may be employed to determine whether the altered phenotype results from mutations within the heterologous portion of the genome.

10

#### **EXAMPLE 19**

##### **Use of GBV-B as Model for HCV**

GBV-B and/or GBV-B/HCV chimeras can be used as a model for HCV. Such  
15 studies will allow one to investigate the mechanisms for the different biological properties of these viruses and to discover and investigate potential inhibitors of specific HCV activities (*e.g.*, proteinase) required for HCV replication.

#### **EXAMPLE 20**

##### **Use of GBV-B/HCV Chimeras to Test Candidate HCV NS3 Proteinase Inhibitors or Other Inhibitors of HCV**

GBV-B/HCV viruses can be used in preclinical testing of candidate HCV NS3  
proteinase inhibitors or other inhibitors of HCV.

##### **25 1. Candidate Substances**

As used herein the term "candidate substance" refers to any molecule that is capable of modulating HCV NS3 proteinase activity or any other activity related to HCV infection. The candidate substance may be a protein or fragment thereof, a small molecule inhibitor, or even a nucleic acid molecule. It may prove to be the case that the  
30 most useful pharmacological compounds for identification through application of the

screening assay will be compounds that are structurally related to other known modulators of HCV NS3 proteinase activity. The active compounds may include fragments or parts of naturally-occurring compounds or may be only found as active combinations of known compounds that are otherwise inactive. However, prior to testing  
5 of such compounds in humans or animal models, it will be necessary to test a variety of candidates to determine which ones have potential.

Accordingly, the active compounds may include fragments or parts of naturally-occurring compounds or may be found as active combinations of known compounds that  
10 are otherwise inactive. As such, the present invention provides screening assays to identify agents that are capable of inhibiting proteinase activity in a cell infected with chimeric GBV-B/HCV viruses containing the HCV proteinase. It is proposed that compounds isolated from natural sources, such as animals, bacteria, fungi, plant sources, including leaves and bark, and marine samples may be assayed as candidates for the  
15 presence of potentially useful pharmaceutical agents. It will be understood that the pharmaceutical agents to be screened could also be derived or synthesized from chemical compositions or man-made compounds. Thus, it is understood that the candidate substance identified by the present invention may be polypeptide, polynucleotide, small molecule inhibitors or any other compounds that may be designed through rational drug  
20 design starting from known inhibitors of proteinases or from structural studies of the HCV proteinase.

The candidate screening assays are simple to set up and perform. Thus, in assaying for a candidate substance, after obtaining a chimeric GBV-B/HCV virus with  
25 infectious properties, a candidate substance can be incubated with cells infected with the virus, under conditions that would allow measurable changes in infection by the virus to occur. In this fashion, one can measure the ability of the candidate substance to prevent or inhibit viral replication, in relationship to the replication ability of the virus in the absence of the candidate substance. In this fashion, the ability of the candidate inhibitory  
30 substance to reduce, abolish, or otherwise diminish viral infection may be determined.

“Effective amounts” in certain circumstances are those amounts effective to reproducibly reduce infection by the virus in comparison to the normal infection level. Compounds that achieve significant appropriate changes in activity will be used.

- 5 Candidate compounds can be administered by any of a wide variety of routes, such as intravenously, intraperitoneally, intramuscularly, orally, or any other route typically employed.

- 10 It will, of course, be understood that all the screening methods of the present invention are useful in themselves notwithstanding the fact that effective candidates may not be found. The invention provides methods of screening for such candidates, not solely methods of finding them.

## 2. *In vitro* Assays

- 15 In one particular embodiment, the invention encompasses *in vitro* screening of candidate substances. Using a cell line that can propagate GBV-B in culture, *in vitro* screening can be used such that GBV-B or HCV virus production or some indicator of viremia is monitored in the presence of candidate compounds. A comparison between the absence and presence of the candidate can identify compounds with possible preventative  
20 and therapeutic value.

## 3. *In Vivo* Assays

- The present invention also encompasses the use of various animal models to test for the ability of candidate substances to inhibit infection by HCV. This form of testing  
25 may be done in tamarins.

- The assays previously described could be extended to whole animal studies in which the chimeric virus could be used to infect a GBV-B permissive primate, such as a tamarin. One would then look for suppression of viral replication in the animal, and a  
30 possible impact on liver disease related to replication of the infectious chimeric virus.

any disease-the reasoning here is that the genetic backbone of the chimera that encodes the nonstructural proteins of GBV-B has not evolved for replication in human cells and thus may not replicate well. Thus, the chimera may have limited replication ability, cause no disease, but still elicit immunity to the surface envelope proteins of HCV and thus have potential as a hepatitis C vaccine. These chimeras can be tested for their ability to promote immunity to HCV through an immune response.

## EXAMPLE 22

### Construction of a GBV-B Infectious Clone

A genome-length cDNA copy of the complete GB virus B (GBV-B) genome sequence, including the novel 3' terminal sequence, was assembled from fragments amplified by reverse transcription-polymerase chain reaction (RT-PCR) from viral RNA present in a 0.2 µl aliquot of infectious serum (GB agent pool mystrax 666, 8/93) supplied by Dr. Jens Bukh of the National Institutes of Health. The serum sample was diluted with 100 µl of fetal calf serum and extracted using the Trizol system (GIBCO/BRL). The pellet was dissolved in 10 mM dithiothreitol containing 20 u/mL RNasin (Promega). The selection of primers for cDNA synthesis and PCR amplification was based on the published sequence of GBV-B (Simons et al., 1995). RT/PCR was carried out using Superscript Reverse Transcriptase (GIBCO/BRL) and the Advantage cDNA PCR Kit (Clontech). Four subgenomic regions were amplified covering the entire published GBV-B genome sequence. A fifth subgenomic region included the novel 3' terminal sequence that was identified in our laboratory. The oligonucleotide primer sets (listed 5'→3') used for amplification of the individual regions included:

Primer 1:

CGGGATCCCGTAATACGACTCACTATAGACCACAAACACTCCAGTTTG

(SEQ ID NO:3)

Primer 2: GTGGAATTACAGCGTCATA

(SEQ ID NO:4)

(Places a T7 RNA polymerase promoter sequence immediately upstream of the GBV-B sequence; the amplified segment extends from the 5' terminus of the viral genome to the unique *EcoRI* site at position 1978.)

5 Primer 3: TGTGAATTCCACTCTCCTACC (SEQ ID NO:5)

Primer 4: TTATCGATTGCAGCAACCATG (SEQ ID NO:6)

(Overlapping *EcoRI* site at position 1978 and the unique *ClaI* site at 5327.)

Primer 5: CATGGTTGCTGCAATCGATAAGCTGAAGAGTACAATAAC

10 (SEQ ID NO:7)

Primer 6: GACAACAGACGCTTGACACG (SEQ ID NO:8)

(Overlapping the *ClaI* site at 5327 and a unique *SalI* site at 7847 in the published sequence: however, the *SalI* site was not present in the amplified GBV-B sequence, and was thus introduced into the cDNA using the QuikChange Site-directed Mutagenesis Kit (Stratagene).)

15

Primer 7: CTGTCATGGGAGATGCGTAC (SEQ ID NO:9)

Primer 8: CGAGCTCGAGCACATCGCGGGGTCGTTAAGCCCGGGGTCTCC

(SEQ ID NO:10)

20 (Overlapping the *SalI* site at 7847 and the published 3' end of the genome.)

Primer 9: GACAACAGACGCTTGACACG (SEQ ID NO:11)

Primer 10:

CCGACTCGAGAATTCGGCCCTGCAGGCCACAACAGTCTCGCGAGTTTTTAATT

25 CCAAGCGGGGGTTGCCCTCCGCTTGGAACAAAAACCGGGGTGCAGCCCTTGG  
TAC (SEQ ID NO:12)

(Overlaps product of primers 7 and 8 and extends to the novel 3' terminal sequence; includes an *XhoI* site at the 3' terminus of the GBV-B sequence to aid subsequent manipulations.)

RT-PCR products were gel-purified using the QIAquick Gel Extraction Kit (Qiagen) and ligated into a plasmid vector with the PstBlue-1 Perfectly Blunt Cloning Kit (Novagene). Bacterial colonies were screened for plasmid DNAs with the correct insert size. Those harboring an insert of the approximate correct size were subjected to diagnostic restriction analysis. cDNA inserts generating the appropriate restriction patterns were sequenced in both directions using an ABI DNA sequencer, and those with sequences closest to the published GBV-B sequence (Simons *et al.*, 1995) were selected for subsequent assembly into the full-length clone.

The cloned overlapping cDNA fragments were assembled into the pACNR1180 plasmid using the unique restriction sites noted in the primer descriptions. The final, fully assembled plasmid bearing a 9.4 kb cDNA GBV-B insertion was subjected to DNA sequencing to confirm the validity of the construction and the absence of any mutations or errors in the sequence that may have been introduced during the assembly process. The sequence of the GBV-B infectious cDNA is shown in SEQ ID NO:2.

Plasmid DNA containing the GBV-B cDNA was purified by isopycnic centrifugation on a CsCl gradient and isolated by ethanol precipitation. The plasmid DNA was linearized at the 3' terminus of the cDNA insert by digestion with *Xho* I. Two µg of the linearized DNA was used as template in an *in vitro* transcription reaction using the Ambion T7 MEGAscript Kit according to the manufacturer's instructions. The integrity of the resultant synthetic RNA product was confirmed by nondenaturing agarose gel electrophoresis.

Approximately 60 µg of RNA transcribed from the GBV-B cDNA clone was diluted in phosphate buffered saline and injected under direct visualization at laparotomy into the liver of a healthy tamarin without a prior history of GBV-B infection (*Saguinus oedipus*). Serum samples were collected from the animal weekly beginning at 2 weeks
